## RAPID QUANTITATIVE ANALYSIS OF PROTEINS OR PROTEIN FUNCTION IN COMPLEX MIXTURES

10

15

This invention was made through funding from the National Science Foundation Science and Technology Center for Molecular Biotechnology (grants 5T32HG and BIR9214821) and the National Institutes of Health (NIH grants RR11823, T32HG00035, HD-02274 and GM60184). The United States government has certain rights in this invention.

20

### CROSS-REFERENCE TO RELATED APPLICATIONS

25

This application takes priority under 35 U.S.C. §119(e) from U.S. provisional applications serial no. 60/097,788, filed August 25, 1998 and serial no. 60/099,113, filed September 3, 1998, both of which are incorporated in their entirety by reference herein.

30

### BACKGROUND OF THE INVENTION

35

40

45

50

55

Genomic technology has advanced to a point at which, in principle, it has become possible to determine complete genomic sequences and to quantitatively measure the mRNA levels for each gene expressed in a cell. For some species the complete genomic sequence has now been determined, and for one strain of the yeast *Saccharomyces cerevisiae*, the mRNA levels for each expressed gene have been precisely quantified under different growth conditions (Velculescu et al., 1997). Comparative cDNA array analysis and related technologies have been used to determine induced changes in gene expression at the mRNA level by concurrently monitoring the expression level of a large number of genes (in some cases all the genes) expressed by the investigated cell or tissue (Shaon et al., 1996). Furthermore, biological and computational techniques have been used to correlate specific function with gene sequences. The interpretation of the data obtained by these techniques in the context of the structure, control and mechanism of biological systems has been recognized as a considerable challenge. In particular, it has been extremely difficult to explain the mechanism of biological processes by genomic analysis alone.

5

10

15

20

Proteins are essential for the control and execution of virtually every biological process. The rate of synthesis and the half-life of proteins and thus their expression level are also controlled post-transcriptionally. Furthermore, the activity of proteins is frequently modulated by post-translational modifications, in particular protein phosphorylation, and dependent on the association of the protein with other molecules including DNA and proteins. Neither the level of expression nor the state of activity of proteins is therefore directly apparent from the gene sequence or even the expression level of the corresponding mRNA transcript. It is therefore essential that a complete description of a biological system include measurements that indicate the identity, quantity and the state of activity of the proteins which constitute the system. The large-scale (ultimately global) analysis of proteins expressed in a cell or tissue has been termed proteome analysis (Pennington et al., 1997).

25

30

35

40

45

50

55

At present no protein analytical technology approaches the throughput and level of automation of genomic technology. The most common implementation of proteome analysis is based on the separation of complex protein samples most commonly by two-dimensional gel electrophoresis (2DE) and the subsequent sequential identification of the separated protein species (Ducret et al., 1998; Garrels et al., 1997; Link et al., 1997; Shevchenko et al., 1996; Gygi et al., 1999; Boucherie et al., 1996). This approach has been revolutionized by the development of powerful mass spectrometric techniques and the development of computer algorithms which correlate protein and peptide mass spectral data with sequence databases and thus rapidly and conclusively identify proteins (Eng et al., 1994; Mann and Wilm, 1994; Yates et al., 1995). This technology has reached a level of sensitivity which now permits the identification of essentially any protein which is detectable by conventional protein staining methods including silver staining (Figeys and Aebersold, 1998; Figeys et al., 1996; Figeys et al., 1997; Shevchenko et al., 1996). However, the sequential manner in which samples are processed limits the sample throughput, the most sensitive methods have been difficult to automate and low abundance proteins, such as regulatory proteins, escape detection without prior enrichment, thus effectively limiting the dynamic range of the technique. In the 2DE/(MS)N method, proteins are quantified by densitometry of stained spots in the 2DE gels.

5

10

15

20

25

The development of methods and instrumentation for automated, data-dependent electrospray ionization (ESI) tandem mass spectrometry (MS<sup>n</sup>) in conjunction with microcapillary liquid chromatography (μLC) and database searching has significantly increased the sensitivity and speed of the identification of gel-separated proteins. As an alternative to the 2DE/MS<sup>n</sup> approach to proteome analysis, the direct analysis by tandem mass spectrometry of peptide mixtures generated by the digestion of complex protein mixtures has been proposed (Dongre et al., 1997). μLC-MS/MS has also been used successfully for the large-scale identification of individual proteins directly from mixtures without gel electrophoretic separation (Link et al., 1999; Opitek et al., 1997). While these approaches dramatically accelerate protein identification, the quantities of the analyzed proteins cannot be easily determined, and these methods have not been shown to substantially alleviate the dynamic range problem also encountered by the 2DE/MS/MS approach. Therefore, low abundance proteins in complex samples are also difficult to analyze by the μLC/MS/MS method without their prior enrichment.

30

It is therefore apparent that current technologies, while suitable to identify the components of protein mixtures, are neither capable of measuring the quantity nor the state of activity of the protein in a mixture. Even evolutionary improvements of the current approaches are unlikely to advance their performance sufficiently to make routine quantitative and functional proteome analysis a reality.

35

40

This invention provides methods and reagents that can be employed in proteome analysis which overcome the limitations inherent in traditional techniques. The basic approach described can be employed for the quantitative analysis of protein expression in complex samples (such as cells, tissues, and fractions thereof), the detection and quantitation of specific proteins in complex samples, and the quantitative measurement of specific enzymatic activities in complex samples.

45

50

In this regard, a multitude of analytical techniques are presently available for clinical and diagnostic assays which detect the presence, absence, deficiency or excess of a protein or protein function associable with a normal or disease state. While these techniques are quite sensitive, they do not necessarily provide chemical speciation of

55

5 products and may, as a result, be difficult to use for assaying several proteins or enzymes  
simultaneously in a single sample. Current methods may not distinguish among aberrant  
10 expression of different enzymes or their malfunctions which lead to a common set of clinical  
symptoms. The methods and reagents herein can be employed in clinical and diagnostic  
assays for simultaneous (multiplex) monitoring of multiple proteins and protein reactions.

#### 15 SUMMARY OF THE INVENTION

This invention provides analytical reagents and mass spectrometry-based methods  
using these reagents for the rapid, and quantitative analysis of proteins or protein function  
in mixtures of proteins. The analytical method can be used for qualitative and particularly  
20 for quantitative analysis of global protein expression profiles in cells and tissues, i.e. the  
quantitative analysis of proteomes. The method can also be employed to screen for and  
identify proteins whose expression level in cells, tissue or biological fluids is affected by a  
stimulus (e.g., administration of a drug or contact with a potentially toxic material), by a  
25 change in environment (e.g., nutrient level, temperature, passage of time) or by a change  
in condition or cell state (e.g., disease state, malignancy, site-directed mutation, gene  
knockouts) of the cell, tissue or organism from which the sample originated. The proteins  
identified in such a screen can function as markers for the changed state. For example,  
30 comparisons of protein expression profiles of normal and malignant cells can result in the  
identification of proteins whose presence or absence is characteristic and diagnostic of the  
malignancy.

35 In an exemplary embodiment, the methods herein can be employed to screen for  
changes in the expression or state of enzymatic activity of specific proteins. These  
changes may be induced by a variety of chemicals, including pharmaceutical agonists or  
40 antagonists, or potentially harmful or toxic materials. The knowledge of such changes may  
be useful for diagnosing enzyme-based diseases and for investigating complex regulatory  
networks in cells.

45 The methods herein can also be used to implement a variety of clinical and  
diagnostic analyses to detect the presence, absence, deficiency or excess of a given  
protein or protein function in a biological fluid (e.g., blood), or in cells or tissue. The  
50

5 method is particularly useful in the analysis of complex mixtures of proteins, i.e., those containing 5 or more distinct proteins or protein functions.

10 The inventive method employs affinity-labeled protein reactive reagents that allow for the selective isolation of peptide fragments or the products of reaction with a given protein (e.g., products of enzymatic reaction) from complex mixtures. The isolated peptide  
15 fragments or reaction products are characteristic of the presence of a protein or the presence of a protein function, e.g., an enzymatic activity, respectively, in those mixtures. Isolated peptides or reaction products are characterized by mass spectrometric (MS) techniques. In particular, the sequence of isolated peptides can be determined using  
20 tandem MS (MS<sup>n</sup>) techniques, and by application of sequence database searching techniques, the protein from which the sequenced peptide originated can be identified. The reagents also provide for differential isotopic labeling of the isolated peptides or reaction products which facilitates quantitative determination by mass spectrometry of the  
25 relative amounts of proteins in different samples. Also, the use of differentially isotopically-labeled reagents as internal standards facilitates quantitative determination of the absolute amounts of one or more proteins or reaction products present in the sample.

30 In general, the affinity labeled protein reactive reagents of this invention have three portions: an affinity label (A) covalently linked to a protein reactive group (PRG) through a linker group (L):

#### 35 A-L-PRG

The linker may be differentially isotopically labeled, e.g., by substitution of one or more  
40 atoms in the linker with a stable isotope thereof. For example, hydrogens can be substituted with deuteriums or C<sup>12</sup> with C<sup>13</sup>.

The affinity label A functions as a molecular handle that selectively binds covalently  
45 or non-covalently, to a capture reagent (CR). Binding to CR facilitates isolation of peptides, substrates or reaction products tagged or labeled with A. In specific embodiments, A is a strepavidin or avidin. After affinity isolation of affinity tagged materials, some of which may be isotopically labeled, the interaction between A and the  
50

capture reagent is disrupted or broken to allow MS analysis of the isolated materials. The affinity label may be displaced from the capture reagent by addition of displacing ligand, which may be free A or a derivative of A, or by changing solvent (e.g., solvent type or pH) or temperature conditions or the linker may be cleaved chemically, enzymatically, thermally or photochemically to release the isolated materials for MS analysis.

Two types of PRG groups are specifically provided herein: (a) those groups that selectively react with a protein functional group to form a covalent or non-covalent bond tagging the protein at specific sites, and (b) those that are transformed by action of the protein, e.g., that are substrates for an enzyme. In specific embodiments, PRG is a group having specific reactivity for certain protein groups, such as specificity for sulfhydryl groups, and is useful in general for selectively tagging proteins in complex mixtures. A sulfhydryl specific reagent tags proteins containing cysteine. In other specific embodiments, PRG is an enzyme substrate that is selectively cleaved (leaving A-L) or modified (giving A-L-PRG) by the action of an enzyme of interest.

Exemplary reagents have the general formula:

where:

A is the affinity label;

PRG is the protein reactive group;

$X^1$ ,  $X^2$ ,  $X^3$  and  $X^4$ , independently of one another, and  $X^2$  independently of other  $X^2$  in the linker group, can be selected from O, S, NH, NR,  $NRR''$ , CO, COO, COS, S-S, SO,  $SO_2$ , CO-NR', CS-NR', Si-O, aryl or diaryl groups or  $X^1$ - $X^4$  may be absent, but preferably at least one of  $X^1$ - $X^4$  is present;

$B^1$  and  $B^2$ , independently of one another, are optional moieties that can facilitate bonding of the A or PRG group to the linker or prevent undesired cleavage of those groups from the linker and can be selected, for example, from COO, CO, CO-NR', CS-NR' and may contain one or more  $CH_2$  groups alone or in combination with other groups, e.g.  $(CH_2)_a$ -CONR',  $(CH_2)_a$ -CS-NR', or  $(CH_2)_a$ ;

5

n, m, p and q are whole numbers that can have values from 0 to about 100, preferably one of n, m, p or q is not 0 and x is also a whole number that can range from 0 to about 100 where the sum of  $n+xm+p+q$  is preferably less than about 100 and more preferably less than about 20;

10

R is an alkyl, alkenyl, alkynyl, alkoxy or aryl group; and

R' is a hydrogen, an alkyl, alkenyl, alkynyl, alkoxy or aryl group.

15

One or more of the  $\text{CH}_2$  groups of the linker can be optionally substituted with small (C1-C6) alkyl, alkenyl, or alkoxy groups, an aryl group or can be substituted with functional groups that promote ionization, such as acidic or basic groups or groups carrying permanent positive or negative charge. One or more single bonds connecting  $\text{CH}_2$  groups in the linker can be replaced with a double or a triple bond. Preferred R and R' alkyl, alkenyl, alkynyl or alkoxy groups are small having 1 to about 6 carbon atoms.

20

25

One or more of the atoms in the linker can be substituted with a stable isotope to generate one or more substantially chemically identical, but isotopically distinguishable reagents. For example, one or more hydrogens in the linker can be substituted with deuterium to generate isotopically heavy reagents.

30

In an exemplary embodiment the linker contains groups that can be cleaved to remove the affinity tag. If a cleavable linker group is employed, it is typically cleaved after affinity tagged peptides, substrates or reaction products have been isolated using the affinity label together with the CR. In this case, any isotopic labeling in the linker preferably remains bound to the protein, peptide, substrate or reaction product.

35

40

Linker groups include among others: ethers, polyethers, ether diamines, polyether diamines, diamines, amides, polyamides, polythioethers, disulfides, silyl ethers, alkyl or alkenyl chains (straight chain or branched and portions of which may be cyclic), aryl, diaryl or alkyl-aryl groups. Aryl groups in linkers can contain one or more heteroatoms (e.g., N, O or S atoms).

45

50

55

5

10

15

20

25

30

In one aspect, the invention provides a mass spectrometric method for identification and quantitation of one or more proteins in a complex mixture which employs affinity labeled reagents in which the PRG is a group that selectively reacts with certain groups that are typically found in peptides (e.g., sulfhydryl, amino, carboxy, homoserine lactone groups). One or more affinity labeled reagents with different PRG groups are introduced into a mixture containing proteins and the reagents react with certain proteins to tag them with the affinity label. It may be necessary to pretreat the protein mixture to reduce disulfide bonds or otherwise facilitate affinity labelling. After reaction with the affinity labeled reagents, proteins in the complex mixture are cleaved, e.g., enzymatically, into a number of peptides. This digestion step may not be necessary, if the proteins are relatively small. Peptides that remain tagged with the affinity label are isolated by an affinity isolation method, e.g., affinity chromatography, via their selective binding to the CR. Isolated peptides are released from the CR by displacement of A or cleavage of the linker, and released materials are analyzed by liquid chromatography/mass spectrometry (LC/MS). The sequence of one or more tagged peptides is then determined by MS<sup>n</sup> techniques. At least one peptide sequence derived from a protein will be characteristic of that protein and be indicative of its presence in the mixture. Thus, the sequences of the peptides typically provide sufficient information to identify one or more proteins present in a mixture.

35

40

45

50

Quantitative relative amounts of proteins in one or more different samples containing protein mixtures (e.g., biological fluids, cell or tissue lysates, etc.) can be determined using chemically identical, affinity tagged and differentially isotopically labeled reagents to affinity tag and differentially isotopically label proteins in the different samples. In this method, each sample to be compared is treated with a different isotopically labeled reagent to tag certain proteins therein with the affinity label. The treated samples are then combined, preferably in equal amounts, and the proteins in the combined sample are enzymatically digested, if necessary, to generate peptides. Some of the peptides are affinity tagged and in addition tagged peptides originating from different samples are differentially isotopically labeled. As described above, affinity labeled peptides are isolated, released from the capture reagent and analyzed by (LC/MS). Peptides characteristic of their protein origin are sequenced using MS<sup>n</sup> techniques allowing identification of proteins in the samples. The relative amounts of a given protein in each sample is determined by comparing relative abundance of the ions

55

5 generated from any differentially labeled peptides originating from that protein. The method  
can be used to assess relative amounts of known proteins in different samples. Further,  
since the method does not require any prior knowledge of the type of proteins that may be  
10 present in the samples, it can be used to identify proteins which are present at different  
levels in the samples examined. More specifically, the method can be applied to screen for  
and identify proteins which exhibit differential express in cells, tissue or biological fluids. It is  
also possible to determine the absolute amounts of specific proteins in a complex mixture. In  
15 this case, a known amount of internal standard, one for each specific protein in the mixture to  
be quantified, is added to the sample to be analyzed. The internal standard is an affinity  
tagged peptide that is identical in chemical structure to the affinity tagged peptide to be  
quantified except that the internal standard is differentially isotopically labeled, either in the  
20 peptide or in the affinity tag portion, to distinguish it from the affinity tagged peptide to be  
quantified. The internal standard can be provided in the sample to be analyzed in other  
ways. For example, a specific protein or set of proteins can be chemically tagged with an  
isotopically-labeled affinity tagging reagent. A known amount of this material can be added  
25 to the sample to be analyzed. Alternatively, a specific protein or set of proteins may be  
labeled with heavy atom isotopes and then derivatized with an affinity tagging reagent.

30 Also, it is possible to quantify the levels of specific proteins in multiple samples in a  
single analysis (multiplexing). In this case, affinity tagging reagents used to derivatize  
proteins present in different affinity tagged peptides from different samples can be selectively  
35 quantified by mass spectrometry.

In this aspect of the invention, the method provides for quantitative measurement of  
specific proteins in biological fluids, cells or tissues and can be applied to determine global  
40 protein expression profiles in different cells and tissues. The same general strategy can be  
broadened to achieve the proteome-wide, qualitative and quantitative analysis of the state of  
modification of proteins, by employing affinity reagents with differing specificity for reaction  
with proteins. The method and reagents of this invention can be used to identify low  
45 abundance proteins in complex mixtures and can be used to selectively analyze specific  
groups or classes of proteins such as membrane or cell surface proteins, or proteins  
contained within organelles, sub-cellular fractions, or biochemical fractions such as  
50

5 immunoprecipitates. Further, these methods can be applied to analyze differences in  
expressed proteins in different cell states. For example, the methods and reagents herein  
can be employed in diagnostic assays for the detection of the presence or the absence of  
10 one or more proteins indicative of a disease state, such as cancer.

In a second aspect, the invention provides a MS method for detection of the presence  
or absence of a protein function, e.g., an enzyme activity, in a sample. The method can also  
15 be employed to detect a deficiency or excess (over normal levels) of protein function in a  
sample. Samples that can be analyzed include various biological fluids and materials,  
including tissue and cells. In this case, the PRG of the affinity labeled reagent is a substrate  
20 for the enzyme of interest. Affinity labeled substrates are provided for each enzyme of  
interest and are introduced into a sample where they react to generate affinity labeled  
products, if the enzyme of interest is present in the sample. Products or unreacted substrate  
that are tagged with the affinity label are isolated by an affinity isolation method, e.g., affinity  
25 chromatography, via their selective binding to the CR. The isolated tagged substrates and  
products are analyzed by mass spectrometry. Affinity labeled products include those in  
which the substrate is entirely cleaved from the linker or in which the substrate is modified by  
reaction with a protein of interest. Detection of the affinity-labeled product indicates the  
30 protein function is present in the sample. Detection of little or no affinity labeled product  
indicates deficiency or absence, respectively, of the protein function in the sample.

35 The amount of selected protein, e.g., measured in terms of enzyme activity, present in  
a sample can be measured by introducing a known amount of an internal standard which is  
an isotopically labeled analog of the expected product of the enzymatic reaction of the  
reagent substrate. The internal standard is substantially chemically identical to the expected  
40 enzymatic reaction product, but is isotopically distinguishable therefrom. The level of protein  
function (e.g., enzymatic activity) in a given sample can be compared with activity levels in  
other samples or controls (either negative or positive controls). The procedure therefore can  
detect the presence, absence, deficiency or excess of a protein function in a sample. The  
45 method is capable of quantifying the velocity of an enzymatic reaction since it enables the  
amount of product formed over a known time period to be measured. This method can be  
multiplexed, by simultaneous use of a plurality of affinity labeled substrates selective for  
50

5 different protein functions and if quantitation is desired by inclusion of the corresponding internal standards for expected products, to analyze for a plurality of protein functions in a single sample.

#### 10 DETAILED DESCRIPTION OF THE INVENTION

15 The methods of this invention employ affinity tagged protein reactive reagents in which the affinity tag is covalently attached to a protein reactive group by a linker. The linker can be isotopically labeled to generate pairs or sets of reagents that are substantially chemically identical, but which are distinguishable by mass. For example a pair of reagents, one of which is isotopically heavy and the other of which is isotopically light can be employed for the comparison of two samples one of which may be a reference sample containing one or more known proteins in known amounts. For example, any one or more of the hydrogen, nitrogen, oxygen or sulfur atoms in the linker may be replaced with their isotopically stable isotopes:  $^2\text{H}$ ,  $^{13}\text{C}$ ,  $^{15}\text{N}$ ,  $^{17}\text{O}$  or  $^{34}\text{S}$ .

25 Suitable affinity tags bind selectively either covalently or non-covalently and with high affinity to a capture reagent (CR). The CR-A interaction or bond should remain intact after extensive and multiple washings with a variety of solutions to remove non-specifically bound components. The affinity tag binds minimally or preferably not at all to components in the assay system, except CR, and does not significantly bind to surfaces of reaction vessels. Any non-specific interaction of the affinity tag with other components or surfaces should be disrupted by multiple washes that leave CR-A intact. Further, it must be possible to disrupt the interaction of A and CR to release peptides, substrates or reaction products, for example, by addition of a displacing ligand or by changing the temperature or solvent conditions. Preferably, neither CR or A react chemically with other components in the assay system and both groups should be chemically stable over the time period of an assay or experiment. The affinity tag preferably does not undergo peptide-like fragmentation during (MS)<sup>n</sup> analysis. The affinity label is preferably soluble in the sample liquid to be analyzed and the CR should remain soluble in the sample liquid even though attached to an insoluble resin such as Agarose. In the case of CR term soluble means that CR is sufficiently hydrated or otherwise solvated such that it functions properly for binding to A. CR or CR-containing conjugates should not be present in the sample to be analyzed, except when added to capture A.

5

Examples of A and CR pairs include:

10

d-biotin or structurally modified biotin-based reagents, including d-iminobiotin, which bind to proteins of the avidin/streptavidin, which may, for example, be used in the forms of strepavidin-Agarose, oligomeric-avidin-Agarose, or monomeric-avidin-Agarose;

15

any 1,2-diol, such as 1,2-dihydroxyethane ( $\text{HO}-\text{CH}_2-\text{CH}_2-\text{OH}$ ), and other 1,2-dihydroxyalkanes including those of cyclic alkanes, e.g., 1,2-dihydroxycyclohexane which bind to an alkyl or aryl boronic acid or boronic acid esters, such as phenyl- $\text{B}(\text{OH})_2$  or hexyl- $\text{B}(\text{OEt})_2$  which may be attached via the alkyl or aryl group to a solid support material, such as Agarose;

20

25

maltose which binds to maltose binding protein (as well as any other sugar/sugar binding protein pair or more generally to any ligand/ligand binding protein pairs that has properties discussed above);

30

a hapten, such as dinitrophenyl group, for any antibody where the hapten binds to an anti-hapten antibody that recognizes the hapten, for example the dinitrophenyl group will bind to an anti-dinitrophenyl-IgG;

35

a ligand which binds to a transition metal, for example, an oligomeric histidine will bind to  $\text{Ni}(\text{II})$ , the transition metal CR may be used in the form of a resin bound chelated transition metal, such as nitrilotriacetic acid-chelated  $\text{Ni}(\text{II})$  or iminodiacetic acid-chelated  $\text{Ni}(\text{II})$ ;

40

glutathione which binds to glutathione-S-transferase.

45

In general, any A-CR pair commonly used for affinity enrichment which meets the suitability criteria discussed above. Biotin and biotin-based affinity tags are preferred. Of particular interest are structurally modified biotins, such as d-iminobiotin, which will elute from avidin or strepavidin columns under solvent conditions compatible with ESI-MS analysis,

50

55

5 such as dilute acids containing 10-20% organic solvent. It is expected that d-iminobiotin  
tagged compounds will elute in solvents below pH 4. d-Iminobiotin tagged protein reactive  
10 reagents can be synthesized by methods described herein for the corresponding biotin  
tagged reagents.

15 A displacement ligand, DL, is optionally used to displace A from CR. Suitable DLs are  
not typically present in samples unless added. DL should be chemically and enzymatically  
stable in the sample to be analyzed and should not react with or bind to components (other  
than CR) in samples or bind non-specifically to reaction vessel walls. DL preferably does  
20 not undergo peptide-like fragmentation during MS analysis, and its presence in sample  
should not significantly suppress the ionization of tagged peptide, substrate or reaction  
product conjugates.

25 DL itself preferably is minimally ionized during mass spectrometric analysis and the  
formation of ions composed of DL clusters is preferably minimal. The selection of DL,  
depends upon the A and CR groups that are employed. In general, DL is selected to  
displace A from CR in a reasonable time scale, at most within a week of its addition, but  
30 more preferably within a few minutes or up to an hour. The affinity of DL for CR should be  
comparable or stronger than the affinity of the tagged compounds containing A for CR.  
Furthermore, DL should be soluble in the solvent used during the elution of tagged  
compounds containing A from CR. DL preferably is free A or a derivative or structural  
35 modification of A. Examples of DL include, d-biotin or d-biotin derivatives, particularly those  
containing groups that suppress cluster formation or suppress ionization in MS.

40 The linker group (L) should be soluble in the sample liquid to be analyzed and it  
should be stable with respect to chemical reaction, e.g., substantially chemically inert, with  
components of the sample as well as A and CR groups. The linker when bound to A should  
not interfere with the specific interaction of A with CR or interfere with the displacement of A  
45 from CR by a displacing ligand or by a change in temperature or solvent. The linker should  
bind minimally or preferably not at all to other components in the system, to reaction vessel  
surfaces or CR. Any non-specific interactions of the linker should be broken after multiple  
washes which leave the A-CR complex intact. Linkers preferably do not undergo peptide-like  
50

5 fragmentation during (MS)<sup>n</sup> analysis. At least some of the atoms in the linker groups should  
be readily replaceable with stable heavy-atom isotopes. The linker preferably contains  
10 groups or moieties that facilitate ionization of the affinity tagged reagents, peptides,  
substrates or reaction products.

To promote ionization, the linker may contain acidic or basic groups, e.g., COOH,  
15 SO<sub>3</sub>H, primary, secondary or tertiary amino groups, nitrogen-heterocycles, ethers, or  
combinations of these groups. The linker may also contain groups having a permanent  
charge, e.g., phosphonium groups, quaternary ammonium groups, sulfonium groups,  
chelated metal ions, tetralkyl or tetraryl borate or stable carbanions.

20 The covalent bond of the linker to A or PRG should typically not be unintentionally  
cleaved by chemical or enzymatic reactions during the assay. In some cases it may be  
desirable to cleave the linker from the affinity tag A or from the PRG, for example to facilitate  
25 release from an affinity column. Thus, the linker can be cleavable, for example, by chemical,  
thermal or photochemical reaction. Photocleavable groups in the linker may include the 1-(2-  
nitrophenyl)-ethyl group. Thermally labile linkers may, for example, be a double-stranded  
duplex formed from two complementary strands of nucleic acid, a strand of a nucleic acid  
30 with a complementary strand of a peptide nucleic acid, or two complementary peptide  
nucleic acid strands which will dissociate upon heating. Cleavable linkers also include those  
having disulfide bonds, acid or base labile groups, including among others, diarylmethyl or  
35 trimethylarylmethyl groups, silyl ethers, carbamates, oxyesters, thiesters, thionoesters, and  
 $\alpha$ -fluorinated amides and esters. Enzymatically cleavable linkers can contain, for example,  
protease-sensitive amides or esters,  $\beta$ -lactamase-sensitive  $\beta$ -lactam analogs and linkers that  
are nuclease-cleavable, or glycosidase-cleavable.

40 The protein reactive group (PRG) can be a group that selectively reacts with certain  
protein functional groups or is a substrate of an enzyme of interest. Any selectively reactive  
protein reactive group should react with a functional group of interest that is present in at  
45 least a portion of the proteins in a sample. Reaction of PRG with functional groups on the  
protein should occur under conditions that do not lead to substantial degradation of the  
compounds in the sample to be analyzed. Examples of selectively reactive PRGs suitable

5 for use in the affinity tagged reagents of this invention, include those which react with  
sulfhydryl groups to tag proteins containing cysteine, those that react with amino groups,  
10 carboxylate groups, ester groups, phosphate reactive groups, and aldehyde and/or ketone  
reactive groups or, after fragmentation with CNBr, with homoserine lactone.

Thiol reactive groups include epoxides,  $\alpha$ -haloacyl group, nitriles, sulfonated alkyl or  
15 aryl thiols and maleimides. Amino reactive groups tag amino groups in proteins and include  
sulfonyl halides, isocyanates, isothiocyanates, active esters, including tetrafluorophenyl  
esters, and N-hydroxysuccinimidyl esters, acid halides, and acid anhydrides. In addition,  
20 amino reactive groups include aldehydes or ketones in the presence or absence of  $\text{NaBH}_4$  or  
 $\text{NaCNBH}_3$ .

Carboxylic acid reactive groups include amines or alcohols in the presence of a  
25 coupling agent such as dicyclohexylcarbodiimide, or 2,3,5,6-tetrafluorophenyl trifluoroacetate  
and in the presence or absence of a coupling catalyst such as 4-dimethylaminopyridine; and  
transition metal-diamine complexes including  $\text{Cu(II)}$ phenanthroline

30 Ester reactive groups include amines which, for example, react with homoserine  
lactone.

35 Phosphate reactive groups include chelated metal where the metal is, for example  
 $\text{Fe(III)}$  or  $\text{Ga(III)}$ , chelated to, for example, nitrilotriacetic acid or iminodiacetic acid.

40 Aldehyde or ketone reactive groups include amine plus  $\text{NaBH}_4$  or  $\text{NaCNBH}_3$ , or these  
reagents after first treating a carbohydrate with periodate to generate an aldehyde or ketone.

45 PRG groups can also be substrates for a selected enzyme of interest. The enzyme of  
interest may, for example, be one that is associated with a disease state or birth defect or  
one that is routinely assayed for medical purposes. Enzyme substrates of interest for use  
with the methods of this invention include, acid phosphatase, alkaline phosphatase, alanine  
aminotransferase, amylase, angiotensin converting enzyme, aspartate aminotransferase,  
50 creatine kinase, gamma-glutamyltransferase, lipase, lactate dehydrogenase, and

5 glucose-6-phosphate dehydrogenase which are currently routinely assayed by other methods.

10 The requirements discussed above for A, L, PRG, extend to the corresponding to the segments of A-L-PRG and the reaction products generated with this reagent.

15 Internal standards, which are appropriately isotopically labelled, may be employed in the methods of this invention to measure absolute quantitative amounts of proteins in samples. Internal standards are of particular use in assays intended to quantitate affinity tagged products of enzymatic reactions. In this application, the internal standard is chemically identical to the tagged enzymatic product generated by the action of the enzyme on the affinity tagged enzyme substrate, but carries isotope labels which may include  $^2\text{H}$ ,  $^{13}\text{C}$ ,  $^{15}\text{N}$ ,  $^{17}\text{O}$ ,  $^{18}\text{O}$ , or  $^{34}\text{S}$ , that allow it to be independently detected by MS techniques. Internal standards for use in method herein to quantitative one or several proteins in a sample are prepared by reaction of affinity labeled protein reactive reagents with a known protein to generate the affinity tagged peptides generated from digestion of the tagged protein. Affinity tagged peptides internal standards are substantially chemically identical to the corresponding affinity tagged peptides generated from digestion of affinity tagged protein, except that they are differentially isotopically labeled to allow their independent detection by MS techniques.

35 The method of this invention can also be applied to determine the relative quantities of one or more proteins in two or more protein samples, the proteins in each sample are reacted with affinity tagging reagents which are substantially chemically identical but differentially isotopically labeled. The samples are combined and processed as one. The relative quantity of each tagged peptide which reflects the relative quantity of the protein from which the peptide originates is determined by the measurement of the respective isotope peaks by mass spectrometry.

45 The methods of this invention can be applied to the analysis or comparison of multiple different samples. Samples that can be analyzed by methods of this invention include cell homogenates; cell fractions; biological fluids including urine, blood, and cerebrospinal fluid; tissue homogenates; tears; feces; saliva; lavage fluids such as lung or peritoneal lavages;

5 mixtures of biological molecules including proteins, lipids, carbohydrates and nucleic acids generated by partial or complete fractionation of cell or tissue homogenates.

10 The methods of this invention employ MS and (MS)<sup>n</sup> methods. While a variety of MS and (MS)<sup>n</sup> are available and may be used in these methods, Matrix Assisted Laser Desorption Ionization MS (MALDI/MS) and Electrospray Ionization MS (ESI/MS) methods are preferred.

#### 15 **Quantitative proteome analysis**

This method is schematically illustrated in Scheme 1 using a biotin labeled sulfhydryl-reactive reagent for quantitative protein profile measurements in a sample protein mixture and a reference protein mixture. The method comprises the following steps:

25 Reduction. Disulfide bonds of proteins in the sample and reference mixtures are reduced to free SH groups. The preferred reducing agent is tri-*n*-butylphosphine which is used under standard conditions. Alternative reducing agents include mercaptoethylamine and dithiothreitol. If required, this reaction can be performed in the presence of solubilizing agents including high concentrations of urea and detergents to maintain protein solubility. The reference and sample protein mixtures to be compared are processed separately, applying identical reaction conditions;

35 Derivatization of SH groups with an affinity tag. Free SH groups are derivatized with the biotinylating reagent biotinyl-iodoacetylaminidyl-4,7,10 trioxatridecanediamine the synthesis of which is described below. The reagent is prepared in different isotopically labeled forms by substitution of linker atoms with stable isotopes and each sample is derivatized with a different isotopically labeled form of the reagent. Derivatization of SH groups is preferably performed under slightly basic conditions (pH 8.5) for 90 min at RT. For the quantitative, comparative analysis of two samples, one sample each (termed reference sample and sample) are derivatized as illustrated in Scheme 1 with the isotopically light and the isotopically heavy form of the reagent, respectively. For the comparative analysis of several samples one sample is designated a reference to which the other samples are related to. Typically, the reference sample is labeled with the isotopically heavy reagent and

5

the experimental samples are labeled with the isotopically light form of the reagent, although this choice of reagents is arbitrary. These reactions are also compatible with the presence of high concentrations of solubilizing agents;

10

15

Combination of labeled samples. After completion of the affinity tagging reaction defined aliquots of the samples labeled with the isotopically different reagents (e.g., heavy and light reagents) are combined and all the subsequent steps are performed on the pooled samples. Combination of the differentially labeled samples at this early stage of the procedure eliminates variability due to subsequent reactions and manipulations. Preferably equal amounts of each sample are combined;

20

25

Removal of excess affinity tagged reagent. Excess reagent is adsorbed, for example, by adding an excess of SH-containing beads to the reaction mixture after protein SH groups are completely derivatized. Beads are added to the solution to achieve about a 5-fold molar excess of SH groups over the reagent added and incubated for 30 min at RT. After the reaction the beads are removed by centrifugation;

30

35

Protein digestion. The proteins in the sample mixture are digested, typically with trypsin. Alternative proteases are also compatible with the procedure as in fact are chemical fragmentation procedures. In cases in which the preceding steps were performed in the presence of high concentrations of denaturing solubilizing agents the sample mixture are diluted until the denaturant concentration is compatible with the activity of the proteases used. This step may be omitted in the analysis of small proteins;

40

45

Affinity isolation of the affinity tagged peptides by interaction with a capture reagent. The biotinylated peptides are isolated on avidin-agarose. After digestion the pH of the peptide samples is lowered to 6.5 and the biotinylated peptides are immobilized on beads coated with monomeric avidin (Pierce). The beads are extensively washed. The last washing solvent includes 10% methanol to remove residual SDS. Biotinylated peptides are eluted from avidin-agarose, for example, with 0.3% formic acid at pH 2;

50

55

5

10

Analysis of the isolated, derivatized peptides by  $\mu$ LC-MS<sup>n</sup> or CE-MS<sup>n</sup> with data dependent fragmentation. Methods and instrument control protocols well-known in the art and described, for example, in Ducret et al., 1998; Figeys and Aebersold, 1998; Figeys et al., 1996; or Haynes et al., 1998 are used.

15

20

25

30

35

In this last step, both the quantity and sequence identity of the proteins from which the tagged peptides originated can be determined by automated multistage MS. This is achieved by the operation of the mass spectrometer in a dual mode in which it alternates in successive scans between measuring the relative quantities of peptides eluting from the capillary column and recording the sequence information of selected peptides. Peptides are quantified by measuring in the MS mode the relative signal intensities for pairs of peptide ions of identical sequence that are tagged with the isotopically light or heavy forms of the reagent, respectively, and which therefore differ in mass by the mass differential encoded within the affinity tagged reagent. Peptide sequence information is automatically generated by selecting peptide ions of a particular mass-to-charge ( $m/z$ ) ratio for collision-induced dissociation (CID) in the mass spectrometer operating in the MS<sup>n</sup> mode. (Link, A.J. et al. (1997), Gygi, S.P. et al. (1999), and Gygi, S.P. et al. (1999)). The resulting CID spectra are then automatically correlated with sequence databases to identify the protein from which the sequenced peptide originated. Combination of the results generated by MS and MS<sup>n</sup> analyses of affinity tagged and differentially labeled peptide samples therefore determines the relative quantities as well as the sequence identities of the components of protein mixtures in a single, automated operation.

40

Results of this applying this method using the biotinylated sulfhydryl reagent and to the quantitative analysis of synthetic peptide samples, to the relative quantitation of the peptides in a protein digest and the tandem mass spectral analysis of a derivatized peptide are shown in Fig. 1, Table 1, and Fig. 2, respectively.

45

This method can also be practiced using other affinity tags and other protein reactive groups, including amino reactive groups, carboxyl reactive groups, or groups that react with homoserine lactones.

35

40

45

The approach employed herein for quantitative proteome analysis is based on two principles. First, a short sequence of contiguous amino acids from a protein (5-25 residues) contains sufficient information to uniquely identify that protein. Protein identification by MS<sup>n</sup> is accomplished by correlating the sequence information contained in the CID mass spectrum with sequence databases, using sophisticated computer searching algorithms (Eng, J. et al. (1994); Mann, M. et al. (1994); Qin, J. et al. (1997); Clauser, K.R. et al. (1995)). Second, pairs of identical peptides tagged with the light and heavy affinity tagged reagents, respectively, (or in analysis of more than two samples, sets of identical tagged peptides in which each set member is differentially isotopically labeled) are chemically identical and therefore serve as mutual internal standards for accurate quantitation. The MS measurement readily differentiates between peptides originating from different samples, representing for example different cell states, because of the difference between isotopically distinct reagents attached to the peptides. The ratios between the intensities of the differing weight components of these pairs or sets of peaks provide an accurate measure of the relative abundance of the peptides (and hence the proteins) in the original cell pools because the MS intensity response to a given peptide is independent of the isotopic composition of the reagents (De Leenheer, A.P. et al (1992). The use of isotopically labeled internal standards is standard practice in quantitative mass spectrometry and has been exploited to great advantage in, for example, the precise quantitation of drugs and metabolites in bodily fluids (De Leenheer, A.P. et al. (1992).

In another illustration of the method, two mixtures consisting of the same six proteins at known, but different, concentrations were prepared and analyzed. The protein mixtures were labeled, combined and treated as schematically illustrated in Scheme 1. The isolated, tagged peptides were quantified and sequenced in a single combined  $\mu$ LC-MS and  $\mu$ LC-MS<sup>n</sup> experiment on an ESI ion trap mass spectrometer. All six proteins were unambiguously identified and accurately quantified (Table 2). Multiple tagged peptides were encountered for each protein. The differences between the observed and expected quantities for the six proteins ranged between 2 and 12%.

50

55

5 ions characterized by the mass differential encoded in the affinity tagged reagent are  
detected in this scan and indicated with their respective  $m/z$  values. The scan shown was  
acquired in 1.3 s. Over the course of the one-hour chromatographic elution gradient, more  
10 than 1200 such scans were automatically recorded. Fig. 3B shows an expanded view of the  
mass spectrum around the ion pair with  $m/z$  ratios of 993.8 and 977.7, respectively. Co-  
elution and a detected mass differential of four units potentially identifies the ions as a pair of  
15 doubly charged affinity tagged peptides of identical sequence (mass difference of eight and a  
charge state of two). Fig. 3C shows the reconstructed ion chromatograms for these two  
species. The relative quantities were determined by integrating the contour of the respective  
peaks. The ratio (light/heavy) was determined as 0.54 (Table 1). The peaks in the  
20 reconstructed ion chromatograms appear serrated because in every second scan the mass  
spectrometer switched between the MS and the MS<sup>n</sup> modes to collect sequence information  
(CID mass spectrum) of a selected peptide ion. These CID spectra were used to identify the  
protein from which the tagged peptides originated. Fig. 4A shows the CID spectrum  
25 recorded from the peptide ion with  $m/z = 998$  (marked with an arrow in Fig. 3A). Database  
searching with this CID spectrum identified the protein as glyceraldehyde-3-phosphate  
dehydrogenase (Fig. 4B) which was a member of the protein mixture.

30 Several beneficial features of this method are apparent. First, at least two  
peptides were detected from each protein in the mixture. Therefore, both quantitation and  
protein identification can be redundant. Second, the identified peptides all contained at least  
35 one tagged cysteinyl residue. The presence of the relatively rare cysteinyl residue in a  
peptide adds an additional powerful constraint for database searching (Sechi, S. et al.  
(1998)). Third, tagging and selective enrichment of cysteine-containing peptides significantly  
reduced the complexity of the peptide mixture generated by the concurrent digestion of six  
40 proteins. For this protein mixture, the complexity was reduced from 293 potential tryptic  
peptides to 44 tryptic peptides containing at least one cysteinyl residue. Fourth, the peptide  
samples eluted from the avidin affinity column are directly compatible with analysis by  $\mu$ LC-  
45 MS<sup>n</sup>.

#### Quantitative analysis of protein expression in different cell states

The protein reactive affinity reagent strategy was applied to study differences in steady-state protein expression in the yeast, *S. cerevisiae*, in two non-glucose repressed states (Table 3). Cells were harvested from yeast growing in log-phase utilizing either 2% galactose or 2% ethanol as the carbon source. One-hundred  $\mu$ g of soluble yeast protein from each cell state were labeled independently with the isotopically different affinity tagged reagents. The labeled samples were combined and subjected to the strategy described in Fig. 1. One fiftieth (the equivalent of approximately 2  $\mu$ g of protein from each cell state) of the sample was analyzed.

Glucose repression causes large numbers of proteins with metabolic functions significant to growth on other carbon sources to be minimally expressed (Ronne, H. (1995; Hodges, P.E. et al. (1999)). Growth on galactose or ethanol with no glucose present results in the expression of glucose repressed genes. Table 3 presents a selection of 34 yeast genes encountered in the analysis, but it contains every known glucose-repressed genes that was identified (Mann, M. et al. (1994). Each of these genes would have been minimally expressed in yeast grown on glucose. Genes specific to both growth on galactose (GAL1, GAL10) as well as growth on ethanol (ADH2, ACH1) were detected and quantitated.

The quantitative nature of the method is apparent in the ability to accurately measure small changes in relative protein levels. Evidence of the accuracy of the measurements can be seen by the excellent agreement found by examining ratios for proteins for which multiple peptides were quantified. For example, the five peptides found from PCK1 had a mean ratio  $\pm 95\%$  confidence intervals of  $1.57 \pm 0.15$ , and the percent error was  $< 10\%$ . In addition, the observed changes fit the expected changes from the literature (Ronne, H. 1995; Hodges, P.E. et al. (1999)). Finally, the observed changes are in agreement with the changes in staining intensity for these same proteins examined after two-dimensional gel electrophoresis (data not shown).

The alcohol dehydrogenase family of isozymes in yeast facilitates growth on either hexose sugars (ADH1) and ethanol (ADH2). The gene ADH2 encodes an enzyme that is both glucose- and galactose-repressed and permits a yeast cell to grow entirely on ethanol

5 by converting it into acetaldehyde which enters the TCA cycle (Fig. 5A). In the presence of  
sugar, ADH1 performs the reverse reaction converting acetaldehyde into ethanol. The  
regulation of these isozymes is key to carbon utilization in yeast (Ronne, H. (1995)). The  
10 ability to accurately measure differences in gene expression across families of isozymes is  
sometimes difficult using cDNA array techniques because of cross hybridization (DeRisi, J.L.  
et al. (1997)). The method of this invention applied as illustrated in Fig.1 succeeded in  
measuring gene expression for each isozyme even though ADH1 and ADH2 share 93%  
15 amino acid (88% nucleotide) sequence similarity. This was because the affinity tagged  
peptides from each isozyme differed by a single amino acid residue (valine to threonine)  
which shifted the retention time by more than 2 min and the mass by 2 daltons for the ADH2  
peptides (Fig. 5B). ADH1 was expressed at approximately 2-fold high levels when galactose  
20 was the carbon source compared with ethanol. Ethanol-induction of ADH2 expression  
resulted in more than 200-fold increases compared with galactose-induction.

25 The results described above illustrate that the method of this invention provides  
quantitative analysis of protein mixtures and the identification of the protein components  
therein in a single, automated operation.

30 The method as applied using a sulfhydryl reactive reagent significantly reduces the  
complexity of the peptide mixtures because affinity tagged cysteine-containing peptides are  
selectively isolated. For example, a theoretical tryptic digest of the entire yeast proteome  
35 (6113 proteins) produces 344,855 peptides, but only 30,619 of these peptides contain a  
cysteiny residue. Thus, the complexity of the mixture is reduced, while protein quantitation  
and identification are still achieved. The chemical reaction in of the sulfhydryl reagent with  
protein can be performed in the presence of urea, sodium dodecyl sulfate (SDS), salts and  
40 other chemicals that do not contain a reactive thiol group. Therefore, proteins can be kept in  
solution with powerful stabilizing agents until they are enzymatically digested. The sensitivity  
of the  $\mu$ LC-MS<sup>n</sup> system is dependent of the sample quality. In particular, commonly used  
protein solubilizing agents are poorly compatible or incompatible with MS. Affinity purification  
45 of the tagged peptides completely eliminates contaminants incompatible with MS. The  
quantitation and identification of low abundance proteins by conventional methods requires  
large amounts (milligrams) of starting protein lysate and involves some type of enrichment for

5 these low abundance proteins. Assays described above, start with about 100 µg of protein  
and used no fractionation techniques. Of this, approximately 1/50 of the protein was  
analyzed in a single µLC-MS<sup>n</sup> experiment. This system has a limit of detection of 10-20 fmol  
10 per peptide (Gygi, S.P. et al. (1999)). For this reason, in the assays described which employ  
µLC-MS<sup>n</sup> only abundant proteins are detected. However, the methods of this invention are  
compatible with any biochemical, immunological or cell biological fractionation methods that  
reduce the mixture complexity and enrich for proteins of low abundance while quantitation is  
15 maintained. This method can be redundant in both quantitation and identification if multiple  
cysteines are detected. There is a dynamic range associated with the ability of the method  
to quantitate differences in expression levels of affinity tagged peptides which is dependent  
on both the intensity of the peaks corresponding the peptide pair (or set) and the overall  
20 mixture complexity. In addition, this dynamic range will be different for each type of mass  
spectrometer used. The ion trap was employed in assays described herein because of its  
ability to collect impressive amounts of sequencing information (thousands of proteins can  
potentially be identified) in a data-dependent fashion even though it offers a more limited  
dynamic quantitation range. The dynamic range of the ion trap (based on signal-to-noise  
25 ratios) varied depending on the signal intensity of the peptide pair and complexity of the  
mixture, but differences of up to 100-fold were generally detectable and even larger  
differences could be determined for more abundant peptides. In addition, protein expression  
level changes of more than 100-200-fold still identify those proteins as major potential  
30 contributors to the phenotypic differences between the two original cell states. The method  
can be extended to include reactivity toward other functional groups. A small percentage of  
proteins (8% for *S. cerevisiae*) contain no cysteinyl residues and are therefore missed by  
analysis using reagents with sulfhydryl group specificity (i.e., thiol group specificity). Affinity  
35 tagged reagents with specificities toward functional groups other than sulfhydryl groups will  
also make cysteine-free proteins susceptible to analysis.

40  
45 The methods of this invention can be applied to analysis of low abundance proteins  
and classes of proteins with particular physico-chemical properties including poor solubility,  
large or small size and extreme pI values.

5

10

The prototypical application of the chemistry and method is the establishment of quantitative profiles of complex protein samples and ultimately total lysates of cells and tissues following the preferred method described above. In addition the reagents and methods of this invention have applications which go beyond the determination of protein expression profiles. Such applications include the following:

15

20

Application of amino-reactive or sulfhydryl-reactive, differentially isotopically labeled affinity tagged reagents for the quantitative analysis of proteins in immuno precipitated complexes. In the preferred version of this technique protein complexes from cells representing different states (e.g., different states of activation, different disease states, different states of differentiation) are precipitated with a specific reagent, preferably an antibody. The proteins in the precipitated complex are then derivatized and analyzed as above.

25

30

35

Application of amino-reactive, differentially isotopically labeled affinity tagged reagents to determine the sites of induced protein phosphorylation. In a preferred version of this method purified proteins (e.g., immunoprecipitated from cells under different stimulatory conditions) are fragmented and derivatized as described above. Phosphopeptides are identified in the resulting peptide mixture by fragmentation in the ion source of the ESI-MS instrument and their relative abundances are determined by comparing the ion signal intensities of the experimental sample with the intensity of an included, isotopically labeled standard.

40

45

Amino-reactive, differentially isotopically labeled affinity tagged reagents are used to identify the *N*-terminal ion series in MS<sup>n</sup> spectra. In a preferred version of this application, the peptides to be analyzed are derivatized with a 50:50 mixture of an isotopically light and heavy reagent which is specific for amino groups. Fragmentation of the peptides by CID therefore produce two *N*-terminal ion series which differ in mass precisely by the mass differential of the reagent species used. This application dramatically reduces the difficulty in determining the amino acid sequence of the derivatized peptide.

### Quantitative Analysis of Surface Proteins in Cells and Tissue

The cell exterior membrane and its associated proteins (cell surface proteins) participate in sensing external signals and responding to environmental cues. Changes in the abundance of cell surface proteins can reflect a specific cellular state or the ability of a cell to respond to its changing environment. Thus, the comprehensive, quantitative characterization of the protein components of the cell surface can identify marker proteins or constellations of marker proteins characteristic for a particular cellular state, or explain the molecular basis for cellular responses to external stimuli. Indeed, changes in expression of a number of cell surface receptors such as Her2/neu, erbB, IGF1 receptor, and EGF receptor have been implicated in carcinogenesis and a current immunological therapeutic approach for breast cancer is based on the infusion of an antibody (Herceptin, Genentech, Palo Alto, CA) that specifically recognizes Her2/neu receptor.

Cell surface proteins are also experimentally accessible. Diagnostic assays for cell classification and preparative isolation of specific cells by methods such as cell sorting or panning are based on cell surface proteins. Thus, differential analysis of cell surface proteins between normal and diseased (e.g., cancer) cells can identify important diagnostic or therapeutic targets. While the importance of cell surface proteins for diagnosis and therapy of cancer has been recognized, membrane proteins have been difficult to analyze. Due to their generally poor solubility they tend to be under-represented in standard 2D gel electrophoresis patterns and attempts to adapt 2D electrophoresis conditions to the separation of membrane proteins have met limited success. The method of this invention can overcome the limitations inherent in the traditional techniques.

The analysis of membrane proteins is challenging because they generally are difficult to maintain in solution under conditions that are compatible with high sensitivity analytical instruments such as mass spectrometers. The application of the methods of the present invention to the analysis of membrane proteins is exemplified using human T cell lymphoma cell line Jurkat for membrane protein labeling and extraction and the well characterized human prostate epithelial cell line P69SV40T and two P69SV40T sublines which differ in IGF-1 receptor expression by factor of 10 to exemplify quantitative, differential analysis of membrane proteins.

50

55

5

10

15

20

25

30

35

40

Jurkat cells are an appropriate model system because the cells are easy to grow in large numbers and because the modulation of cell surface proteins in response to different stimuli and experimental conditions has been well characterized in T lymphocytes. Commercially available biotinylation reagents or more generally affinity tagging reagents are employed to derivatize lysine residues and the free N-termini. Water soluble biotinylation reagents such as Sulfo-NHS (N-hydroxy succinimide) biotin and analogs (Sulfosuccinimidyl-6-(biotinamido)-hexanoate, Pierce, Rockford, IL) which have been used extensively for labeling cell surface proteins can be employed. The reaction of NHS esters with primary amines is best at neutral pH values and above and is compatible with the presence of organic solvent such as DMSO or DMF. Biotinylation of cell surface proteins from the Jurkat cells is carried out in PBS buffer at pH 7.2. Cells ( $1 \times 10^7$ ) are washed with PBS buffer to remove contaminating serum and other proteins from the culture medium. The cells are resuspended at  $25 \times 10^6$  cell/ml and reacted with 0.5 mg/ml of Sulfo-NHS-Biotin (Pierce, Rockford, IL) for 30 min at RT. The labeled cells are washed twice with cold PBS to remove unreacted biotinylation reagent. Biotinylated cells are solubilized at  $5 \times 10^7$  cells/ml in lysis buffer containing 1% Triton X-114. Triton X-114 has the property of phase-partitioning into detergent phase and aqueous phase at 30°C. Following the phase partitioning, detergent phase is removed from the aqueous phase by centrifugation at 300xg. Phase partitioning has previously been successfully used to enrich cell membrane. Also, this technique was found to enrich membrane proteins from Jurkat cell lysates. Triton phase is diluted 1:5 (v/v) using 50 mM ammonium bicarbonate buffer, pH 8.5, and high-purity, modified porcine-trypsin is added to digest the proteins at a concentration of 12.5 ng/ml for overnight at 37°C. Trypsin is neutralized by the addition of a cocktail of serine protease inhibitors and tryptic peptides are isolated by the avidin affinity chromatography techniques. Eluted peptides are separated e.g., by  $\mu$ LC methods and identified by searching peptide sequence databases, using for example, the Sequest program.

45

50

The human prostate epithelial cell line P69SV40T which was immortalized with SV 40 T antigen has been well characterized. This cell line is immortal but not tumorigenic and expresses type 1 insulin like growth factor receptor (IGF-1R) at  $2 \times 10^4$  receptors per cell. A subline, called M12, was derived from P69SV40T by sequential passage in male athymic nude mice. This cell line is highly tumorigenic and metastatic and expresses  $1.1 \times 10^3$  IGF-

55

5 1R per cell. The relative difference in the abundance of IGF-1R in the cell lines P69SV40T  
and M12 can be quantitatively determined using methods of this invention adapted for  
application to membrane proteins. Since the number of IGF-1R for these cell lines has  
10 already been determined, this well characterized system can provide a reference to validate  
the efficiency of the quantitative methods of this invention

15 P69SV40T cells ( $1 \times 10^7$ ) are biotinylated with an isotopically heavy biotin tagged  
amino reactive reagent and the M12 cells ( $1 \times 10^7$ ) are biotinylated with a corresponding  
isotopically light amine reactive biotin tagged amino reactive reagent. IGF-1R is then  
immunoprecipitated from the combined lysate of both cell lines using an antibody against  
20 human IGF-1R and the total mass of immunoprecipitated proteins is digested with trypsin.  
Trypsin is then neutralized, e.g., by the addition of inhibitors and tagged peptides are purified  
by biotin-avidin affinity chromatography. The eluted peptides are analyzed by LC-MS and  
LC-MS<sup>N</sup> for peptide quantitation and identification, respectively, as has been described  
25 above. Quantitation in this experiment is facilitated by the option to use selective ion  
monitoring in the MS. In this mode only the masses of tagged peptide ions expected to  
derive from IGF-1R need be monitored.

30 The described technique can be applied to compare the differences in relative  
abundance of cell surface proteins between parental prostate cell line (P69SV40T) and M12  
cells to detect and identify those cell surface proteins whose expression level is different in  
35 the two cell lines and which may be characteristic of the different cell states. Using the  
methods described herein global, relative quantitation of the cell surface proteins in any two  
or more cell lines can be analyzed to detect and identify those cell surface proteins  
characteristic of the different cell states. Results can be independent confirmed using  
40 procedure such as 1D or 2D gels, if applicable, or quantitative western blotting to confirm  
quantitation results.

45 It is expected that the experimental variability of quantitation of cell surface proteins  
will be considerably better than the accuracy of quantitation achieved by currently  
available cDNA array technology. In addition to relative protein quantity and identity, the  
method can also be used to reveal the orientation of the protein in the membrane, based on  
50

5

the presumption that intact, alive cells will exclude the biotinylating reagent.

10

15

20

25

Alternative methods can be applied to enhance the selectivity for tagged peptides derived from cell surface proteins. For example, tagged cell surface proteins can be trypsinized directly on the intact cells to generate tagged peptides, purified and analyzed as discussed. In addition, traditional cell membrane preparations may be used as an initial step to enrich cell surface proteins. These methods can include gentle cell lysis with a dounce homogenizer and series of density gradient centrifugations to isolate membrane proteins prior to proteolysis. This method can provide highly enriched preparations of cell surface proteins. Affinity tagged proteins may also be isolated by affinity chromatography prior to proteolysis as well as after proteolysis. This chromatography can be performed in the presence of surfactants such as TX-100, NP-40 or Tween-20 to maintain protein solubility. The sequential application of affinity chromatography steps (one for the intact protein and one for the tagged peptide fragments) provides a high degree of selectivity. These alternative methods are easily scalable for the detection of low abundance membrane proteins and the relative quantity of tagged peptides tagged is maintained through the selective enrichment steps.

30

In the application of the methods of this invention to cell surface proteins, once the tagged proteins are fragmented, the tagged peptides behave no differently from the peptides generated from more soluble samples.

35

#### **Synthesis of affinity tagged protein reactive reagents that are selective for certain proteins groups**

40

Synthetic routes exemplary affinity tagged reagents suitable for use in the methods of this invention are provided in Schemes 2-3 where well-known synthetic techniques are employed in synthesis of the non-deuterated and deuterated reagents.

45

Biotinyl-iodoacetylamidyl-4,7,10 trioxatridecanediamine 4 (Scheme 3) consists of a biotin group, a chemically inert spacer of capable of being isotopically labelled with stable isotopes and a iodoacetamidyl group, respectively. The biotin group is used for affinity

50

55

5 enrichment of peptides derivatized with the reagent, the ethylene glycol linker is differentially  
isotopically labeled for mass spectral analysis and the iodoacetamidyl group provides  
specificity of the reagent for sulfhydryl-containing peptides. The reagent can be synthesized  
10 in an all hydrogen form (isotopically light form) with and with 1-20, and preferably 4-8  
deuterium atoms in the linker (isotopically heavy forms).

#### 15 Analysis of Velocities of Multiple Enzymes in Cell Lysates

Monitoring enzyme functions by biochemical assays is an essential diagnostic tool  
that employs a multitude of analytical techniques including spectrophotometric, fluorometric,  
and radiometric detection of products. However, current methods are difficult to use for  
20 assaying several enzymes simultaneously in a single sample. Mass spectrometry for  
quantification of a collection of metabolites in biological fluids has emerged as a powerful  
approach for the analysis of birth defects (Morris et al., 1994), but this analytical technique  
has not been developed for the direct analysis of rates of individual enzymatic steps. The  
25 analytical method described herein for monitoring and quantification of enzymatic activities in  
cell homogenates and other biological samples permits simultaneous (multiplex) monitoring  
of multiple reactions, and can be readily automated.

30 A feature of the method of this invention as applied to enzyme assays is the use of  
electrospray ionization mass spectrometry (ESI-MS) (Cole et al., 1997) for the simultaneous  
detection of enzymatic products and chemically identical internal standards, which are  
distinguished by stable isotope (deuterium) labeling. A second feature is the use of affinity  
35 tagged reagents containing an enzyme substrate which when combined with affinity  
purification provide for facile capture of enzymatic products from crude biological fluids. The  
affinity tagged reagents are designed to contain a target substrate for an enzyme of interest  
that is covalently attached to an affinity tag via a linker. Action of the enzyme of interest on  
40 the substrate conjugate causes cleavage or other modification that changes its molecular  
mass (Scheme 4). The change of mass is detected by ESI-MS. The linker and affinity  
tag used preferably facilitate ionization by ESI, block action of other enzymes in the  
45 biological fluid, and allow highly selective capture from the complex matrix for facile  
purification.

5 An example of this approach is the design and synthesis of affinity tagged enzyme  
substrate reagents 1 and 2 (Scheme 5) to simultaneously assay lysosomal  $\beta$ -galactosidase  
and N-acetyl- $\alpha$ -D-glucosaminidase, respectively. Deficiency of the former enzyme results in  
10 one of the lysosomal storage diseases, GM<sub>1</sub>-gangliosidosis, a condition that occurs in the  
population with a frequency of about 1 in 50,000 and leads to early death of affected  
children. Deficiency of N-acetyl-R-D-glucosaminidase results in the rare lysosomal storage  
disorder Sanfilippo syndrome type B. This example has been described in Gerber et al.  
15 (1999) J. Amer. Chem. Soc. 121: 1102-1103 which is incorporated by reference herein in  
its entirety.

20 Conjugates 1 and 2 consist of biotin as an affinity tag, which is coupled to sarcosine.  
Biotin allows highly specific capture of the substrate conjugate through non-covalent binding  
to streptavidin immobilized on agarose beads (Bayer et al., 1990). Sarcosine provides an N-  
methylated amide linkage to biotin to block the enzyme biotinidase, which is often present in  
25 the cellular fluids and could cause cleavage of the conjugate molecule during the assay  
(Wilbur et al., 1997). In addition, it was found that biotinyl-sarcosine conjugates can be  
displaced from streptavidin by addition of biotin. The N-biotinylsarcosine block is linked to a  
polyether diamine, the length of which can be varied to avoid mass/charge overlaps of  
30 products and internal standards. The linker also allows facile introduction of multiple  
deuterium atoms (i.e., 8 deuteriums in 5 and 4 in 6, Scheme 5) to permit the synthesis of  
internal standards. The d8-linker was made by reacting DOCH<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>OD with  
CD<sub>2</sub> d<sub>2</sub>CD<sub>2</sub> in benzene with catalytic NaOD (Ashikaga, K.; Ito, S.; Yamamoto, M.; Nishijima,  
35 Y. *Bull. Chem. Soc. Jpn.* 1988, 61, 2443-2450) and the resulting dinitrile was reduced to the  
diamine with Ra-Ni. The d4-linker was made in the same way using ethylene glycol and CD<sub>2</sub>  
d<sub>2</sub>CD<sub>2</sub> in CH<sub>3</sub>CN and catalytic NaOH.

40 In addition, the linker is hydrophilic to ensure good water solubility of the substrate  
conjugate, and it has basic groups which are efficiently protonated by ESI and thus ensure  
sensitive detection by mass spectrometry. The target carbohydrate substrates are attached  
45 to the polyether linker by a  $\beta$ -alanine unit (Scheme 5). The enzymatic product conjugates 3  
and 4 are also shown Scheme 5. Conjugates 1 and 2 were prepared as shown in Scheme 5.  
All reagents were purified to homogeneity by reverse-phase HPLC and characterized by  
50

5 high-field  $^1\text{H}$  NMR and ESI-MS. The substrate was linked to the diamine spacer by Michael  
addition of the latter onto the p-acryloylamidophenyl glycoside, (Romanowska et al., 1994)  
10 and the intermediate was coupled with the tetrafluorophenyl ester of N-biotinylsarcosine  
(Wilbur et al., 1997).

15 The ESI-MS assay of  $\beta$ -galactosidase and N-acetyl-R-D-glucosaminidase is based on  
enzymatic cleavage of the glycosidic bond to release monosaccharide and conjugates 3 and  
4 (mass differences are 162 and 203 Da, respectively). In a typical procedure, 0.2 mM 1 and  
0.3 mM 2 were incubated with sonicated cultured fibroblasts from individual patients with  $\beta$ -  
galactosidase deficiency and with fibroblasts cultured from unaffected people. After  
20 incubation, labeled internal standards 5 and 6 were added, and the biotinylated components  
were captured on streptavidin-agarose beads. Quantitative streptavidin capture efficiency  
from a cell homogenate was observed with model reagents. After purification by multiple  
washings to remove nonspecifically bound components, the biotinylated products were  
25 released by free biotin, and the eluant was analyzed by ESI-MS. About 85% release of the  
biotinylated products was observed after incubation with excess biotin for 90 min. A blank  
was obtained by quenching the assay with all components present at time zero.

30 A typical procedure, cell protein (75  $\mu\text{g}$ ) in 15  $\mu\text{L}$  of water was added to 15  $\mu\text{L}$  buffer  
(0.1 M Na citrate, pH 4.25) containing 2 (0.3 mM) and 1 (0.2 mM, added 5 h after addition of  
cell protein). After incubation for 5.5 h at 37  $^\circ\text{C}$ , the reaction was quenched by addition of  
35 200  $\mu\text{L}$  of 0.2 M glycine carbonate buffer, pH 10.3, and 5 and 6 (1 nmol each) were added.  
After centrifugation to remove cell debris, the supernatant was loaded onto a bed of  
streptavidin-agarose (7 nmol biotin binding capacity, Pierce) in a small filtration device (micro  
BioSpin, Bio-Rad). After 5 min, filtration was effected by centrifugation, and the gel bed was  
40 washed with 0.1% Triton X-100 (about 1 min incubation, then spin) and then six times with  
purified water (Milli-Q, Millipore). Elution was carried out in 25  $\mu\text{L}$  of 50% methanol containing  
56 nmol of free biotin (1-10 h incubation, then spin). Filtrate was diluted 4-fold with 50%  
45 methanol/water, and 1  $\mu\text{L}$  was analyzed by ESI-MS.

50 The ESI-MS spectrum of the blank (Figure XA) is remarkably simple, showing peaks of  
the  $(\text{M} + \text{H})^+$  ions from reagents 1 and 2 ( $m/z$  843 and 840), internal standards 5 and 6 ( $m/z$

5 689 and 641), and trace amounts of products 3 and 4 ( $m/z$  681 and 637). Ions due to clusters of biotin also appear in the spectrum but did not interfere with the analysis. The presence of nondeuterated products in the blank may be due to nonenzymatic substrate  
10 reagent hydrolysis during sample work up or to collision-induced dissociation of the substrate ion in the gas phase. A MS/MS spectrum of the (conjugate 1 + H)<sup>+</sup> ion at  $m/z$  843 gave a prominent fragment of (conjugate 3 + H)<sup>+</sup> at  $m/z$  681 (spectrum not shown). The ESI-MS spectrum of a sample incubated with cell homogenate from a healthy individual clearly shows  
15 the  $\beta$ -galactosidase product at  $m/z$  681 and the N-acetyl- $\alpha$ -D-glucosaminidase product at  $m/z$  637 (Figure XB). Triplicate enzymatic reactions using cells from a healthy patient yielded a  $\beta$ -galactosidase specific activity of  $51 \pm 3$  nmol/h/(mg cell protein) and an N-acetyl- $\alpha$ -D-glucosaminidase specific activity of  $1.4 \pm 0.3$  nmol/h/mg. Time course studies confirmed that  
20 the initial reaction velocities were being measured. Values obtained with cells from six healthy individuals ranged from  $36 \pm 4$  to  $68 \pm 3$  nmol/h/mg for  $\beta$ -galactosidase and  $0.9 \pm 0.05$  to  $2.3 \pm 0.4$  nmol/h/mg for N-acetyl- $\alpha$ -D-glucosaminidase. In contrast, very little enzymatic product above the blank level ( $0.9 \pm 0.9$  and  $0.8 \pm 0.6$  nmol/h/mg) was observed  
25 when cells from two patients with  $\beta$ -galactosidase deficiency were used, whereas N-acetyl- $\alpha$ -D-glucosaminidase activity is clearly detected (Figure XC). These spectra were obtained with 0.75  $\mu$ g of cell protein, corresponding to  $\sim 1000$  fibroblasts. Thus the ESI-MS method has very high sensitivity for biomedical applications.

ESI-MS was carried out on a Finnigan LCQ ion trap instrument. Data were collected in  
35 full scan mode from  $m/z$  625 to 875 by direct infusion at 1.5  $\mu$ L/min. Specific activities were obtained from the ratio of product to internal standard ion peak areas (averaged over 30 scans).

40 The approach described for assaying enzymes using substrate reagents and ESI-MS can be broadly applied. The multiplex technique can be expanded to assay dozens or more enzymes simultaneously in a single reaction, obviating the need for multiple assays to assist in confirming diagnoses of rare disorders. The method can be used to measure several  
45 enzymes simultaneously when evaluating the rate of chemical flux through a specific biochemical pathway or for monitoring biochemical signaling pathways. The affinity tag-capture reagent method for isolation of affinity tagged reaction products and substrates from complex mixtures is technically simple and can be readily automated, particular when biotin-

5 strepavidin is employed. Because of the high sensitivity of the ESI-MS detection employed,  
which requires only sub-microgram quantities of the substrate reagents per assay, the  
10 synthesis of several hundred substrate reagents on a low-gram scale becomes practical and  
economical. Since most enzyme active sites are exposed to solvent, it is possible to attach  
an affinity tagged linker to most enzyme substrates while preserving enzymatic activity.  
15 Scheme 6 provides the structures of several additional enzyme substrates, suitable for use in  
this method, indicating by arrows allowable positions for tag attachment sites. Allowable tag  
sites for additional enzyme substrates can be determined by review of X-ray crystal  
structures of enzyme-substrate or enzyme-substrate analog structures. Using a standard  
20 computer graphics program, available X-ray data and by attaching an extended chain butyl  
group (as a model for the affinity tagged linker) to potential tag attachment sites, suitable  
attachment sites that show there are no enzyme-atoms in van der Waals overlap with the  
model tag can be predicted.

25 Analogous methods to those described above can be applied to the analysis of  
enzymes associated with other Sanfillipo Syndromes (A, C and D). SFA is associated with  
heparan sulfamidase, SFC is associated with acetyl-CoA-alpha-glucosaminide N-  
30 acetyltransferase and SFD is associated with N-acetylglucosamine 6-sulfatase. Exemplary  
affinity tagged enzyme substrate reagents useful in the analysis of these enzymes and the  
diagnosis of these disorders are provided below. The methods can also be applied of the  
diagnosis of Niemann-Pick Type A and B disease by assaying for acid sphingomyelinase  
35 and to the diagnosis of Krabbe disease by assaying for galactocerebroside beta-  
glactosidase. These enzymes are currently assayed employing fluorophore-derivatized  
reagents as indicated in Scheme 7. Enzyme substrate reagents for assay of these enzymes  
in the methods herein can be readily prepared by replacement of the fluorophore with an A-L  
40 group herein. This approach to preparation of affinity tagged enzyme substrates is generally  
applicable to any known fluorophore -derivatized enzyme substrate or substrate analog.

45 Table 4 provides exemplary enzymes that are associates with certain birth defects or  
disease states. These enzymes can be assayed by the methods described herein.

5  
10  
**Assaying Enzymatic Pathways for Carbohydrate-Deficient Glycoprotein Syndromes (CDGS)**

The methods and reagents of this invention can be employed to quantify the velocities of multiple enzymes pertinent to diagnosis of CDGS diseases.

15  
20  
25  
30  
35  
40  
**CDGS Type Ia and Ib** are caused by the deficiency or absence of the enzymes phosphomannoisomerase (PMIb) (Type Ib) and phosphomannomutase (PMM2) (Type Ia) which are part of a multistep pathway (Scheme 8) for conversion of glucose to mannose-1-phosphate (Freeze, 1998). The monosaccharide substrates involved in the pathway are fructose-6-phosphate, mannose-6-phosphate, and mannose-1-phosphate. These monosaccharides can be somewhat difficult to convert to substrate conjugates because it is not *a priori* clear which atom on the sugar should be conjugated with the linker without impairing enzyme activity. PMIb and PMM2 can, however, be assayed indirectly. Mammalian cell microsomes contain dolichol-P-mannose synthase which catalyzes the reaction of dolichol-phosphate with GDP-mannose to form dolichol-P-mannose and GDP (Scheme 8, Chapman et al. 1980). This synthase can be assayed using the methods of this invention, specifically with a biotin-linker substrate. Microbial PMM and the enzyme which makes GDP-mannose from GTP and mannose-1-P, GDP-mannose pyrophosphorylase, are readily purified from bacteria and yeast (Glaser, 1966, Preiss, 1966), and these enzymes can be supplied exogenously to the enzyme assay. If PMIb activity is deficient, little or no mannose-6-P will be made when the reaction sequence is started by addition of fructose-6-P. Without mannose-6-P, mannose-1-P and GDP-mannose will not be made, and thus no conjugated-dolichol-P-mannose will be detected by ESI-MS. Exogenous GTP is supplied as a requirement for the GDP-mannose pyrophosphorylase step, and ATP is omitted so that mannose-6-P cannot be made from mannose. To assay PMM2, the reaction sequence is initiated with mannose-6-P, and PMM2 deficiency results in the failure to make conjugated-dolichol-P-mannose.

45  
50  
55  
The carrier dolichol is a ~60- to 105-carbon isoprenoid. Evidence is accumulating that many enzymes that operate on carbohydrates attached to dolichol chains are tolerant to significant shortening of the dolichol chain; even 10- and 15-carbon dolichols are tolerated (Rush and Wachter, 1995). It appears that such enzymes act on the water-soluble carbohydrate portion of the dolichol conjugate and thus have little or no requirement to bind

5 the dolichol anchor. Based on this, an affinity labeled substrate for the direct assay of  
dolichol-P-mannose synthase and the indirect assay of PM1b and PMM2 is prepared by  
attaching an affinity labeled linker to the non-polar end of a short dolichol, such as the 10-  
10 carbon dolichol analog citronellol.

The synthesis of a biotinylated dolichol<sub>10</sub>-substrate conjugate containing a sarcosinyl  
linker (B-S-Dol<sub>10</sub>-P) is shown in Scheme 9. Protected citronellol (R = *t*-BuSiMe<sub>2</sub>) is  
15 regioselectively oxidized at the terminal allylic methyl group (McMurry and Kocovsky, 1984),  
and the allylic alcohol is coupled with biotinylsarcosine active ester (R = CH<sub>3</sub>). The citronellol  
1-hydroxy group is subsequently deprotected and phosphorylated with POCl<sub>3</sub> (Rush and  
20 Wachter, 1995). In a parallel synthesis, d<sub>5</sub>-sarcosine, CD<sub>3</sub>NHCD<sub>2</sub>COOH, is used to prepare  
the isotopically labelled (heavy) reagent for use as an internal standard. d<sub>5</sub>-Sarcosine is  
readily prepared from commercially available materials (BrCD<sub>2</sub>COOH and CD<sub>3</sub>NH<sub>2</sub>) using  
standard synthetic techniques.

25 The deuterated internal standard, B-d<sub>5</sub>-S-Dol<sub>10</sub>-P-Mannose, is synthesized  
enzymatically by incubating hen oviduct microsomes with GDP-mannose and the synthetic  
B-d<sub>5</sub>-S-Dol<sub>10</sub>-P substrate conjugate (Rush and Waechler, 1995). An added advantage of the  
30 B-S-conjugate is that it allows for a facile affinity purification of the microsomal mannosylated  
product by specific capture on agarose-streptavidin beads followed by elution with free biotin.

35 This method employing affinity tagged short dolichol analogues is generally  
applicable for assaying other enzymes that operated on dolichol anchored carbohydrates.  
Such an approach is useful for the subsequent identification of enzyme deficiencies present  
40 in other types of CDGS that have not been yet identified.

45 **CDGS Type II** results from defective GlcNAc transferase II (GlcNAc-T II) which  
transfers GlcNAc from UDP-GlcNAc to the 2-position of a mannose residue in the  
intermediate branched oligosaccharide (the Core Region) in the process of building up the  
disialo-biantennary chain (Scheme 10) (Schachter, 1986, Brockhausen et al, 1989). GlcNAc  
transferase II is one of the six known enzymes that mediate highly regiospecific glycosylation  
50 of the mannose residues in the Core Region. The Core Region is anchored at the reducing

5 end to chitobiosylasparagine, where the asparagine residue is part of the peptide chain of  
the glycosylated protein. The latter structure unit in the substrate can be replaced by a  
hydrophobic chain without loss of enzyme activity (Kaur et al, 1991). Thus, the substrate  
10 conjugate for CDGS Type II is assembled by linking a affinity-labelled linker group to the  
reducing end to chitobiosylasparagine. However, the latter structure unit in the substrate can  
be replaced by a hydrophobic chain without loss of enzyme activity (Kaur et al, 1991). For  
example, commercially available  $\alpha$ -D-manno-pyranosylphenylisothiocyanate can be coupled  
15 to a biotin-labelled linker and the 5,6-hydroxyls are selectively protected as illustrated in  
Scheme 11 (Paulsen and Meinjohanns, 1992). Coupling of the equatorial 3-OH with per-O-  
acetylmannosyl-1-trichloroacetamidate (Paulsen et al, 1993) will provide a disaccharide  
conjugate (Scheme 12). If a minor amount of coupling occurs at the axial 2-OH group the  
20 products can be separated by HPLC. After deprotection, the primary 6-OH is coupled with a  
second equivalent of per-O-acetylmannosyl-1-trichloroacetamidate to yield the Core Region  
conjugate. Deprotection of the O-acetyl groups yields the substrate conjugate for GlcNAc  
transferase I which can be converted to the GlcNAc-T II substrate by enzymatic glycosyl  
25 transfer using a Triton X-100 rabbit liver extract, a reaction that has been carried out on a  
preparative scale (Kaur et al. 1981).

30 The synthesis of the deuterium labeled derivative needed for the internal standard is  
performed in parallel by using a labeled PEG-diamine building block (Gerber et al, 1999).  
The biotinylated trisaccharide is converted to the tetrasaccharide (product of GlcNAc-T II) by  
35 incubation with UDP-GlcNAc and transferase II (Kaur and Hindsgaul, 1991, Tan et al, 1996)  
and utilizing the B-S handle for affinity purification of the enzymatic products.

#### CDGS Type V

40 The lipid-linked oligosaccharide (LLO) that is transferred to the Asn residue of the  
glycosylated protein is composed of 2 GlcNAc, 9 mannoses, and 3 glucoses. It has recently  
been shown that microsomes from CDGS type V patients are greatly deficient in the enzyme  
45 that transfers one or more glucose residues during LLO biosynthesis (Korner et al, 1998).  
Since the transferase that attaches the carbohydrate unit of LLO to the Asn residue  
discriminates against the glucose-deficient LLO, CDGS Type V patients have fewer numbers  
of carbohydrate units attached to glycoproteins, such as transferrin (Korner et al, 1998).

5 However, the few carbohydrate units that are present are full-length, demonstrating that residual glucosyl transfer occurs in type V CDGS patients (Korner et al, 1998). Thus, quantification of the rate of Asn glycosylation by ESI-MS would constitute a viable assay of CDGS Type V syndrome.

10 Synthetic peptides with 3-7 amino acid residues containing the Asn-Xaa-Ser/Thr sequence have been shown to be good substrates for glycosylation (Ronin et al., 1981). The strategy for the ESI-MS assay of the oligosaccharide transferase relies on a B-S conjugate of an appropriate peptide containing the Asn-Xaa-Ser/Thr sequence (Scheme 13). A heptapeptide,  $\text{NH}_2\text{-Tyr-Gln-Ser-Asn-Ser-Thr-Met-NH}_2$  has shown high activity in a previous study (Ronin et al, 1981). The peptide is readily available by standard peptide synthesis using an in-house automatic synthesizer. The heptapeptide and its glycoconjugates can be ionized by ESI to provide stable singly-charged ions. Coupling of BS-tetrafluorophenyl ester with  $\text{NH}_2\text{-Tyr-Gln-Ser-Asn-Ser-Thr-Met-NH}_2$  will directly yield the substrate for the transferase. Several products are expected from the enzymatic glycosylation and subsequent modifications of the oligosaccharide antenna. The products can be prepared enzymatically by incubating thyroid rough microsomes with BS-Tyr-Gln-Ser-Asn-Ser-Thr-Met-NH<sub>2</sub> and Dol-P-Glu (Ronin et al, 1981a), followed by affinity purification of the biotinylated products. Product distribution due to different degrees of glycosylation can be monitored by ESI-MS, and the major components can be purified by HPLC. An analogous procedure using a B-N(CD<sub>3</sub>)CD<sub>2</sub>CO- conjugate is used to prepare deuterated internal standards.

35 The molecular masses of the ionized substrate conjugates for the set of enzymes assayed for CDGS Ia, Ib, II, and V syndromes, as well as products and internal standards are compiled in Table 5, which shows that no isobaric overlaps among the (M + H)<sup>+</sup> species occur. The close spacing between the (M + Na)<sup>+</sup> ion from the Type Ia,b product and the (M + H)<sup>+</sup> ion of the demannosylated B-(N-C<sub>2</sub>D<sub>5</sub>)-2,2-D<sub>2</sub>-Gly-Dol<sub>10</sub>-P internal standard can be readily avoided by adjusting the ESI-MS conditions by addition of Na<sup>+</sup> ions to generate the gas phase ions as Na-adducts.

45 All three of the targeted enzymes can be analyzed simultaneously in a single biological sample, such as a cell lysate. The PMM2 and PM1b cannot be assayed

5 simultaneously because they require the addition of different exogeneous substrates.  
Nevertheless, two assays using identical ESI-MS techniques can be used for diagnosing the  
various CDGS types instead of relying on a battery of different methods.

#### 10 Clinical Enzymology Assays

15 A fibroblast cell pellet is thawed on ice. Sufficient 0.9% NaCl is added to give a  
final protein concentration in the lysate of ~ 5mg/ mL (typically 100 mcL), and  
the cell pellet is sonicated in ice water 5 times for 2 seconds each at moderate  
power. Total protein is determined spectrophotometrically using the BCA reagent  
20 (BCA Protein Assay kit, Pierce).

The total enzyme reaction volume is 20  $\pm$  30 mcL. The substrate stock solutions  
25 are maintained at concentrations of 3mM (SFB) and 2mM (GM1). These concentrations  
were measured by <sup>1</sup>H-NMR signal integratin versus an internal standard (formamide  
proton of DMF). Final concentration of substrates is 0.3 and 0.2 mM, respectively. A  
volume of reaction buffer (e.g. 200mM sodium citrate, pH 4.5) equal to the difference of  
30 the substrate addition (2-3 mcL) plus sufficient cell sample volume to equal 50  $\pm$  75mcg  
total protein from 20-30 mcL is added to a 0.5 mL Eppendorf tube, followed by substrate.  
The sample is cooled on ice, and patient cell sample is added. The reaction is initiated by  
incubation at 37 deg C.

35 For SFB: The reaction is allowed to proceed for 4.5  $\pm$  6 hours, after which GM1  
substrate can be added or the reaction can be quenched with 100 mcL of 200mM glycine-  
carbonate buffer, pH 10.5.

40 For GM1: The reaction is allowed to proceed for 0.5 hours. Quenching is as for  
SFB.

45 After quenching, the samples are placed on ice. Internal standards are added  
(1nmol each, i.e. 50 mcL of a 0.02 mM solution). The samples are microfuged at  
-15,000 rpm for 2 min at room temperature to pellet cell debris. Streptavidin-Agarose  
50

5 beads (Immunopure immobilized streptavidin, Pierce) are placed in a micro bio-spin chromatography column (Bio-Rad). Sufficient beads are added to give a total biotin binding capacity of 5 nmol (typical binding capacity 100pmol per mcL of beads as  
10 determined by Pierce). The sample supernatant is transferred to the bio-spin tube and allowed to bind for 10 minutes at room temperature. The sample is spun at ~3,000 rpm to remove excess supernatant, then washed once with 0.01% Triton X-100 and at least five  
15 times with purified water, spinning the tube in-between to remove solution. For each wash, sufficient wash solution is added to fill the bio-spin tube.

20 The purified beads are then treated with 30 mcL purified water, followed by 10 mcL of a 4mM biotin solution. The tubes are capped at the bottom to prevent leakage and allowed to incubate at 2-8°C for 2-12 hours. The samples are spun at ~3,000 rpm to elute the sample into a clean Eppendorf tube.

25 The sample is then diluted with 60 mcL of 50% methanol/water and infused into the ion-trap mass spectrometer. The ESI-MS spectrum is tuned to reduce non-specific cleavage of the samples by first analyzing a blank sample (cell lysate added after reaction  
30 quench). The infused sample is analyzed by ion chromatogram integration of a 1amu-wide window about the (M + H<sup>+</sup>)<sup>+</sup> ions of product and internal standard.

35 Results are reported in nmol product formed/hour of incubation/milligrams total protein in reaction mixtures

#### Clinical Analysis of Patient Samples for GM1 and SFB

40 Patient skin fibroblasts were obtained as frozen pellets, and stored at -20 deg C until use. Two GM1 affected samples and six normal controls were analyzed.

45 50 mcL of 0.9% NaCl was added to each patient cell pellet. The pellets were lysed by sonication in ice water 5x for 2 seconds each at moderate sonication power, chilling the microtip in ice water in between sonications.

5

Samples were quantitated by BCA (Pierce) assay as follows:

10 Reagent A and B were mixed in 50:1 ratio as described. A protein standard curve was prepared using bovine serum albumin as a standard at concentrations of 2, 1, 0.5, 0.2, and 0.05 mg/ mL. A portion of the patient sonicates were diluted 1:15 in water, and 5 mL of each diluted patient sample and standard curve point was added to separate glass culture tubes containing 200 mL water, in duplicate. The samples were then diluted with 15 1 mL of the mixed BCA reagent, vortexed to mix, and incubated at 37 deg C for 60 minutes. The samples were allowed to cool to room temperature, and analyzed against a blank containing only 200 mL water. The samples were analyzed by monitoring 20 absorbance at 562nm in polystyrene cuvettes. Average patient absorbance values were blank corrected and compared to standards via linear regression.

25 The patient protein concentrations were determined to be:

1.(Affected) 12.2mg/ mL, 2. (Normal) 10.8mg/ mL, 3. (Normal) 11.9mg/ mL, 4. (Normal) 12.1mg/ mL, 5. (Normal) 10.3mg/ mL, 6. (Normal) 7.79mg/ mL, 7. (Normal) 15.7mg/ mL, 8. (Affected) 11.4mg/ mL

30 Incubations were performed in a total of 30 mL of total volume. The amount of reaction buffer (200mM sodium citrate, pH 4.25) added to blank Eppendorf tubes was the difference of the substrate volume (3 mL of each substrate stock solution, 2mM for 35 GM1 and 3mM for SFB, for a total of 6 mL) plus the volume of cell lysate required to equal 75mcg total protein, from 30 mL. For example, patient 1. incubation mixture initially contained 3 mL of SFB substrate solution, 6.14 mL patient cell lysate, and 40 17.86 mL reaction buffer. The GM1 substrate was added later in the incubation (see below).

45 Each patient sample was analyzed in triplicate. The reaction mixtures were kept on ice during preparation, and the reaction was initiated by transfer to a 37 deg C water bath. 5.5 hours into the incubation, 3 mL GM1 substrate was added to each reaction, and after an additional 0.5 hours the reactions were placed on ice and quenched with 200 mL

50

55

of a 200mM glycine-carbonate buffer, pH 10.25.

The purification and analysis procedures are as described in Clinical Enzymology Assay (Typical).

The resultant enzyme activities, as an average standard deviation nmol product/hour incubation/mg total protein:

	B-Gal		SFB	
	RATE	+/- SD	Rate	+/- SD
<b>Normals</b>				
Patient 2	68.0	2.6	0.90	0.05
Patient 3	35.5	3.9	1.54	0.38

GM <sub>1</sub> (#8)	0.8	0.6	0.70	0.20

5

The following synthetic method refer to Schemes 14-23  
Synthesis for GM1-gangliosids (beta-D-galactosidase deficiency)

10

1. 2,3,5,6-Tetrafluorophenyl trifluoroacetate (1). 25g (0.15mol) 2,3,5,6-tetrafluorophenol, 35 mL (0.2mol) trifluoroacetic anhydride and 0.5 mL boron trifluoride etherate were refluxed for 18 hours under argon atmosphere. Trifluoroacetic anhydride and trifluoroacetic acid were removed by distillation at room temperature. The trifluoroacetic anhydride fraction was returned to the mixture, and the reaction was refluxed for 24 hours. This was repeated twice. After final distillation at room temperature, the desired product 1 was distilled at reduced pressure (62°C/45mmHg) to produce a colorless liquid (30g, 82%). <sup>1</sup>H-NMR. (Ref. Gamper, H. B., Nucl. Acids Res., v21 pp145-150)
2. Biotin-2,3,5,6-tetrafluorophenyl ester (2) A 2.5g (10.3mmol) quantity of d-biotin in 20 mL anhydrous DMF under argon atmosphere was warmed to 60°C with stirring to effect dissolution. 1.7 mL (12.5mmol) triethylamine was added, followed by 3.4g (12.5mmol) 1. The mixture was stirred for 2 hours, after which the solvent was removed by rotary evaporation. The resultant semi-solid was triturated with 15 mL ether twice to produce a white solid (2.6g, 65%). <sup>1</sup>H-NMR. (Ref. Wilbur, D. S., Bioconj. Chem., v8 pp572-584)
3. N-methylglycylbiotinamide-methyl ester (3) A 2.5g (6.4mmol) quantity of biotin tetrafluorophenyl ester in 30 mL anhydrous DMF under argon atmosphere was added to a mixture of 1.1g (7.7mmol) N-methylglycine methyl ester hydrochloride dissolved in 10 mL anhydrous DMF and 1.25 mL (9.0 mmol) triethylamine. The reaction mixture was stirred at room temperature for 2 hours, then the solvent was removed by rotary evaporation. The residue was extracted with chloroform (2x100 mL), washed with water (2x20 mL), and dried with anhydrous sodium sulfate. The solvent was removed under vacuum to yield 2.1g (98 %) of methyl ester of N-methylglycine biotinamide as an oil. <sup>1</sup>H-NMR. (Ref. Wilbur, D. S., Bioconj. Chem., v8 pp572-584)

35

45

50

55

5 4. N-methylglycylbiotinamide acid (4) N-Methylglycylbiotinamide methyl  
ester was hydrolyzed in a mixture of 31 mL MeOH and 10 mL of 1N  
NaOH at room temperature with stirring for 1 hour. The mixture was  
10 diluted with 50 mL 50% MeOH/water and neutralized with cation  
exchange resin, hydrogen form (AG MP-50, BioRad). The solution was  
filtered, the resin washed (3x50 mL) with 50% MeOH/water, and the  
solvents removed by rotary evaporation to yield 1.6g (90%) of N-  
15 methylglycylbiotinamide acid as an off-white solid. <sup>1</sup>H-NMR. (Ref.  
Wilbur, D. S., Bioconj. Chem., v8 pp572-584)

5. p-Acrylamidophenyl-?-D-galactopyranoside (5) 40mg (0.15mmol) p-  
20 aminophenyl ?-D-galactopyranoside was added to 25 mL methanol  
and 200 mL triethylamine with stirring. The solution was chilled in an  
ice bath. 53.3mg (0.6mmol) acryloyl chloride was dissolved in 5 mL dry  
methylene chloride and added dropwise to the stirred solution over 5  
25 minutes. The reaction was allowed to return to room temperature,  
followed by 2 hours of stirring. The solution was then treated with  
successive anion and cation exchange resins (AG MP-1 and AG MP-  
50, respectively, BioRad) until neutral pH was obtained with moist pH  
30 paper. Solvent was removed by rotary evaporation to yield a solid  
(43mg, 90%). <sup>1</sup>H-NMR. (Ref. Romanowska, A., Methods Enzymol.,  
v242 pp90-101)

6. Michael addition product of 4,7,10-trioxa-1,13-tridecanediamine and 5  
35 (6) 20mg (0.07mmol) 5 was added to a stirred solution of 80mg  
(0.35mmol) 4,7,10-trioxa-1,13-tridecanediamine in 5 mL 0.2M sodium  
carbonate, pH 10.5 at 37°C. The reaction was allowed to proceed for 3  
40 days, after which the solution was neutralized with dilute trifluoroacetic  
acid and purified by reverse-phase HPLC (Vydac C-18 prep-scale  
column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA))  
to give 7.3 mg of product. (Ref. Romanowska, A., Methods Enzymol.,  
45 v242 pp90-101)

7. GM1 substrate conjugate of 4 and 6 (7) A 2.5mg (7.4mmol) quantity  
of 4 was dissolved in 1.5 mL anhydrous DMF with stirring, under argon

5 atmosphere. 5 mL triethylamine was added, followed by 2.3mg  
(8.8mmol) 1. The formation of active ester was monitored by silica  
TLC (5:1 CHCl<sub>3</sub>/CH<sub>3</sub>OH, R<sub>f</sub> 0.5, UV) by briefly drying the spotted TLC  
10 plate with a stream of air. After 25 minutes, the mixture was added to  
3.2mg (5.9mmol) 6 in 1 mL anhydrous DMF. After 2 hours, the  
solvent was removed by vacuum centrifugation and the final product  
was purified by reverse-phase HPLC (Vydac C-18 prep-scale column,  
15 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield  
4.6 mg. (Analogous chemistry, ref. Wilbur, D. S., Bioconj. Chem., v8  
pp572-584)

20 8. 1,2,10,11-octadeutero-3,6,9-trioxa-1,11-undecanedinitrile (8) 1g  
(9.4mmol) of diethylene glycol was dissolved in 2 mL D<sub>2</sub>O in a 10 mL  
round bottom flask under argon atmosphere. The D<sub>2</sub>O was removed by  
rotary evaporation and the process was repeated 4 times. The d-2  
25 diethylene glycol was added with 25 mL dry benzene, followed by  
1.6 g (28.2mmol) d-3 acrylonitrile with stirring under argon atmosphere.  
After 12h, the solvent was removed under reduced pressure and the  
resultant semisolid was extracted with chloroform (2x5 mL). The  
30 solvent was removed by rotary evaporation to yield 1.85g (89%)  
product. (Ref. Ashikaga, K., Bull. Chem. Soc. Jpn., v61 pp2443-2450)

35 9. 2,3,11,12-octadeutero-4,7,10-trioxa-1,13-tridecanediamine (9) Raney  
nickel (Aldrich) was washed five times with anhydrous methanol by  
inversion and decantation. 50mg of the washed catalyst was placed in  
20 mL anhydrous methanol, followed by 1g (4.6mmol) 8 in a 50 mL  
40 screw-cap vial fitted with a Teflon-lined rubber septum. The vial  
headspace was flushed for a few min with H<sub>2</sub> gas via an 18-gauge  
needle piercing the septum. The cap was screwed on tightly and the  
entire assembly was charged to 40psi H<sub>2</sub> and placed in a hot water  
45 bath (80°C) for 4 hours, after which the solid catalyst was removed by  
filtration and the methanol evaporated. The final product was purified  
by reverse-phase HPLC (Vydac C-18 prep-scale column, 6 mL/min.  
Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield 180 mg.

(Ref. Ashikaga, K., Bull. Chem. Soc. Jpn., v61 pp2443-2450)

10. Deuterated analog of 6 (10) 25mg (0.09mmol) 5 was added to a stirred solution of 90mg (0.4mmol) 9 in 5 mL 0.2M sodium carbonate, pH 10.5 at 37°C. The reaction was allowed to proceed for 3 days, after which the solution was neutralized with dilute trifluoroacetic acid and purified by reverse-phase HPLC (Vydac C-18 prep-scale column, 6 mL/min.

Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield 6 mg.

11. Deuterated analog of 7 (11) A 3mg (8.4mcmmol) quantity of 4 was dissolved in 0.7 mL anhydrous DMF with stirring, under argon atmosphere. 5 mL triethylamine was added, followed by 2.4mg (8.9mcmmol) 1. The formation of active ester was monitored by silica TLC (5:1 CHCl<sub>3</sub>/CH<sub>3</sub>OH, R<sub>f</sub> 0.5, UV) by briefly drying the spotted TLC plate with a stream of air. After 25 minutes, the mixture was added to 6mg (11mcmmol) 10 in 1 mL anhydrous DMF. After 2 hours, the solvent was removed by vacuum centrifugation and the final product was purified by reverse-phase HPLC (Vydac C-18 prep-scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield 1.8 mg.

12. GM1 internal standard conjugate (12) 1.8mg 11 was added to 2 mL 100mM Tris/10mM MgCl<sub>2</sub>, pH 7.3 buffer with stirring. 15 units recombinant  $\beta$ -D-galactosidase (Sigma) was added, and after 12 hours the mixture was purified by reverse-phase HPLC (Vydac C-18 prep-scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ACN (0.08%TFA)). Yield 1.5 mg.

#### Polyether diamine linker synthesis (Second Generation)

Synthesis is based on chemistry previously described (Kataky, R. et. al. J CHEM SOC PERK T 2 (2) 321-327 FEB 1990), with minor modifications and an additional two steps. As an example, deviations from the established procedure as well as exact details for the additional steps are outlined below for the starting material diethylene glycol.

5 1,11-Dicyano-3,6,9-trioxaundecane (13) To a stirred solution of 2% (w/v) sodium hydroxide (5 mL) and diethylene glycol (5.3g, 50mmol) was added acrylonitrile (7.95g, 150mmol). The mixture was stirred at room temperature overnight and additioned with  
10 50 mL dichloromethane. The organic layer was washed 2x with brine and dried (MgSO<sub>4</sub>). The solvent was removed by rotary evaporation. The oily residue was treated with 200 proof ethanol, and the solvent was removed by rotary evaporation. This was repeated 2x to remove excess unreacted acrylonitrile. The product was used without further  
15 purification

Diethyl 4,7,10-trioxatridecane-1,13-dioate (14) 2g (9.4mmol) 13, was dissolved  
20 in 5 mL ethanol. 1g conc. sulfuric acid was added slowly, over 5 minutes. The reaction was heated to reflux overnight. The reaction was extracted with 40 mL methylene chloride, washed once with 10 mL water and 3x with 10 mL dilute brine solution. The organic layer was dried (MgSO<sub>4</sub>) and solvent was removed to yield an oil. The final  
25 product was purified by silica chromatography (methylene chloride/ethyl acetate).

1,13-dihydroxy-4,7,10-trioxatridecane (15) Prepared exactly as described, using  
30 tetrahydrofuran as solvent. (1.7g, 5.5mmol 14, 50 mL distilled [CaH<sub>2</sub>] THF, 0.66g, 16.5mmol lithium aluminum hydride). Once addition was complete, excess LAH was quenched with ethanol, and the salts precipitated by dropwise addition of saturated sodium sulfate solution until a white precipitate formed. The solvent was removed, the  
35 precipitate washed 6x 30 mL with THF and the combined organic extracts were evaporated to yield an oil. Final product is purified by silica chromatography (first with methylene chloride then with ethyl acetate and finally with acetone).

40 1,13-dichloro-4,7,10-trioxatridecane (analog using P2) (16) 1.1g, (4.9mmol) 15 was added to 1.15g (14.6mmol) distilled pyridine in 30 mL dry benzene with stirring, followed by 1.8g (14.6mmol) thionyl chloride. The mixture was heated to reflux for 6  
45 hours. After cooling in an ice bath, 5 mL 3M HCl was added with vigorous stirring. The organic layer was separated, washed 3x with a dilute brine solution, and dried (NaSO<sub>4</sub>) to yield a yellowish oil. After washing and removal of solvent, the dichloride was used  
50 without further purification.

5

## Additional steps

10

15

1,13-dicyano-4,7,10-trioxatridecane (17) To a stirred solution of 0.78g (15.5mmol) sodium cyanide in 4 mL dimethyl sulfoxide at 80°C was added 1g (3.9mmol) of 16. After 2 hours, the reaction was additioned with 10 mL of saturated sodium chloride solution, 5 mL of water, and 50 mL ethyl acetate. The organic layer was washed 3x with a brine solution as before, after which the organic layer was dried (Na<sub>2</sub>SO<sub>4</sub>) and the solvents removed. The final product was purified by silica chromatography (methylene chloride/ethyl acetate). ESI-MS: predicted, 240.1; observed, 241.1 (M + H)<sup>+</sup>

20

25

30

1,15-diamino-5,8,11-trioxapentadecane (18) A stirred solution of 50 mL dry THF containing 0.42g (10.4mmol) fresh LAH was heated to gentle reflux under argon for 15 minutes. 0.5g (2mmol) 17 in 15 mL dry THF was added dropwise over 20 minutes, maintaining a gentle reflux. The unreacted LAH was quenched with ethanol, and the mixture was treated with dropwise addition of saturated sodium sulfate under efficient stirring until a white precipitate formed. The mixture was filtered, and the precipitate was washed 6x 30 mL with THF. The organic extracts were combined and the solvent was removed by rotary evaporation to yield an oil. ESI-MS: predicted, 248.1; observed, 249.1 (M + H)<sup>+</sup>

35

## Deuteration

40

Deuterium has been incorporated into the diamine linker by reduction of 14 and 17 using lithium aluminum deuteride (98% D) to achieve a d-8 deuterated diamine. No other aspects of the synthesis were changed for this procedure. These diols are used in the construction of the SFD conjugates as described later.

13. p-Aminophenyl-?-D-N-acetylglucosamine (19) 20mg (0.07mmol) p-

55

5 Nitrophenyl-?-D-N-acetylglucosamine (Sigma) was added to 5mg  
washed palladium catalyst on activated carbon in 3 mL methanol with  
10 stirring in a 5 mL septa-lined vial. The septum was pierced by a 16-  
gauge needle and the vial headspace was flushed with H<sub>2</sub> gas. H<sub>2</sub> gas  
was allowed to slowly bubble through the solution for 2 hours, after  
which the catalyst was removed by filtration over diatomaceous earth  
(Celite). The solvent was removed by rotary evaporation to yield a  
15 semi-solid 18mg (90%).

14. p-Acrylamidophenyl-?-D-N-acetylglucosamine (20) 10mg (0.03mmol)  
19 was added to 15 mL methanol and 100 mL triethylamine with  
20 stirring. The solution was chilled in an ice bath. 15mg (0.17mmol)  
acryloyl chloride was dissolved in 2 mL dry methylene chloride and  
added dropwise to the stirred solution over 5 minutes. The reaction  
25 was allowed to return to room temperature, followed by 2 hours of  
stirring. The solution was then treated with successive anion and  
cation exchange resins (AG MP-1 and AG MP-50, respectively,  
BioRad) until neutral pH was obtained with moist pH paper. Solvent  
30 was removed by rotary evaporation to yield a solid (11mg, 95%). <sup>1</sup>H-  
NMR. Yield 11 mg.

35 15. 3,6-dioxo-1,9-nonanedinitrile (21) 2g (0.032mol) ethylene glycol was  
added to 0.5 g dry potassium hydroxide in 30 mL dry benzene,  
followed by 5g (0.096mmol) acrylonitrile with stirring overnight at room  
temperature. The reaction was filtered and the solvent was removed by  
40 rotary evaporation to yield an oil. Final product was purified by silica  
chromatography (chloroform/methanol) to yield a colorless oil 3.2g  
(60%).

45 16. 4,7-dioxo-1,10-decanediamine (22) Raney nickel (Aldrich) was washed  
five times with anhydrous methanol by inversion and decantation.  
50 50mg of the washed catalyst was placed in 20 mL anhydrous

5 methanol, followed by 1 g (6mmol) 21 in a 50 mL screw-cap vial fitted  
with a Teflon-lined rubber septum. The vial headspace was evacuated  
10 with H<sub>2</sub> gas via an 18-gauge needle piercing the septum. The cap was  
screwed on tightly and the entire assembly was charged to 40psi H<sub>2</sub>  
and placed in a hot water bath (80°C) for 4 hours, after which the solid  
15 catalyst was removed by filtration and the methanol evaporated. The  
final product was purified by reverse-phase HPLC (Vydac C-18 prep-  
scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN  
(0.08%TFA)).

20 17. Michael addition product of 20 and 22 (23) 5mg (0.015mmol) 20 was  
added to a stirred solution of 13mg (0.06mmol) 22 in 5 mL 0.2M  
sodium carbonate, pH 10.5 at 37°C. The reaction was allowed to  
proceed for 3 days, after which the solution was neutralized with dilute  
25 trifluoroacetic acid and purified by reverse-phase HPLC (Vydac C-18  
prep-scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN  
(0.08%TFA)). Yield 6 mg.

30 18. SFB substrate conjugate of 4 and 23 (24) A 4mg (0.013mmol) quantity  
of 4 was dissolved in 1.5 mL anhydrous DMF with stirring, under argon  
atmosphere. 10 mL dry triethylamine was added, followed by 4mg  
35 (0.015mmol) 1. The formation of active ester was monitored by silica  
TLC (5:1 CHCl<sub>3</sub>/CH<sub>3</sub>OH, R<sub>f</sub> 0.5, UV) by briefly drying the spotted TLC  
plate with a stream of air. After 25 minutes, the mixture was added to  
6mg (0.012mmol) 23 in 1 mL anhydrous DMF. After 2 hours, the  
40 solvent was removed by vacuum centrifugation and the final product  
was purified by reverse-phase HPLC (Vydac C-18 prep-scale column,  
6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield  
4.2 mg.

45 19. 1,9-tetradeutero-3,6-dioxo-1,9-nonanedinitrile (25) 0.5g (8mmol)  
ethylene glycol was added to 0.1 g dry potassium hydroxide in 20 mL

5 acetonitrile, followed by 1.4g (24mmol) d-3 acrylonitrile with stirring  
overnight at room temperature. The reaction was filtered and the  
solvent was removed by rotary evaporation to yield an oil. Final  
10 product was purified by silica chromatography (chloroform/methanol) to  
yield a colorless oil 0.9g (65%).

15 20. 1,9-tetradeutero-3,6-dioxo-1,9-nonanediamine (26) Raney nickel  
(Aldrich) was washed five times with anhydrous methanol by inversion  
and decantation. 20mg of the washed catalyst was placed in 30 mL  
anhydrous methanol, followed by 0.5g (3mmol) 25 in a 50 mL screw-  
20 cap vial fitted with a Teflon-lined rubber septum. The vial headspace  
was evacuated with H<sub>2</sub> gas via an 18-gauge needle piercing the  
septum. The cap was screwed on tightly and the entire assembly was  
charged to 40psi H<sub>2</sub> and placed in a hot water bath (80: C) for 4 hours,  
25 after which the solid catalyst was removed by filtration and the  
methanol evaporated. The final product was purified by reverse-phase  
HPLC (Vydac C-18 prep-scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O  
(0.08%TFA)/ ACN (0.08%TFA)).

30 21. Deuterated analog of 23 (27) 20mg (0.07mmol) p-acrylamidophenyl ?-  
D-galactoside was added to a stirred solution of 90mg (0.4mmol) 26 in  
35 5 mL 0.2M sodium carbonate, pH 10.5 at 37°C. The reaction was  
allowed to proceed for 3 days, after which the solution was neutralized  
with dilute trifluoroacetic acid and purified by reverse-phase HPLC  
(Vydac C-18 prep-scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O  
40 (0.08%TFA)/ ACN (0.08%TFA)). Yield 2 mg.

45 22. Deuterated analog of 24 (28) A 2mg (6.3mcmol) quantity of 4 was  
dissolved in 1.5 mL anhydrous DMF with stirring, under argon  
atmosphere. 5 mL triethylamine was added, followed by 2.1mg  
(7.6mcmol) 1. The formation of active ester was monitored by silica  
TLC (5:1 CHCl<sub>3</sub>/CH<sub>3</sub>OH, R<sub>f</sub> 0.5, UV) by briefly drying the spotted TLC  
50

5 plate with a stream of air. After 35 minutes, the mixture was added to  
4mg (7mmol) 27 in 1 mL anhydrous DMF. After 2 hours, the solvent  
was removed by vacuum centrifugation and the final product was  
10 purified by reverse-phase HPLC (Vydac C-18 prep-scale column, 6  
mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield 1.2  
mg.

15 23. SFB internal standard conjugate (29) 1.2mg 28 was added to 2 mL  
100mM Tris/10mM MgCl<sub>2</sub>, pH 7.3 buffer with stirring. 15 units  
recombinant  $\beta$ -D-galactosidase (Sigma) was added, and after 12 hours  
20 the mixture was purified by reverse-phase HPLC (Vydac C-18 prep-  
scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ACN  
(0.08%TFA)). Yield 0.7 mg.

25 Clinical Substrate Synthesis for Sanfilippo Syndrome, type D  
(a sulfatase deficiency)

30 24. p-Acrylamidophenyl- $\beta$ -D-N-acetylglucosamine-6-sulfate (30) 100mg  
(0.28mmol) 20 was added to 10 mL dry DMF under argon atmosphere  
with stirring at room temperature. 89mg (0.56mmol) sulfur trioxide-  
pyridine complex was dissolved in 2 mL dry DMF and was added to  
35 the reaction in 0.7x, 1.1x, 1.3x and 1.9x equivalents (+700 mL, +400  
mL, +200 mL, and +600 mL). The reaction progress was monitored  
by <sup>1</sup>H-NMR shift of the anomeric (C1) proton chemical shift from 5.29  
to 5.24 ppm by removal of 15 mL of solution 1 hour after addition of  
40 each amount of sulfating reagent. The removed mixture was dried by  
vacuum centrifugation and redissolved in d-6 DMSO and analyzed.  
Upon the appearance of more than two forms (starting material and C-  
6 sulfate) of the C1 anomeric proton, the reaction was removed to -  
45 20°C and stored. The product was purified by vacuum centrifugation to  
remove solvent, followed by reverse-phase HPLC (Vydac C-18 prep-  
scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN

5

(0.08%TFA)). Yield 72%.

10

25. Michael addition product of 18 and 30 (31) 25mg (0.058mmol) 30 was added to a stirred solution of 83mg (0.35mmol) 18 in 5 mL 0.2M sodium carbonate, pH 10.5 at 37°C. The reaction was allowed to proceed for 3 days, after which the solution was neutralized with dilute trifluoroacetic acid and purified by reverse-phase HPLC (Vydac C-18 prep-scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield 10 mg.

15

20

26. SFD substrate conjugate of 4 and 31 (32) A 5.7mg (0.018mmol) quantity of 4 was dissolved in 1.0 mL anhydrous DMF with stirring, under argon atmosphere. 20 mL dry triethylamine was added, followed by 5.5mg (0.020mmol) 1. The formation of active ester was monitored by silica TLC (5:1 CHCl<sub>3</sub>/CH<sub>3</sub>OH, R<sub>f</sub> 0.5, UV) by briefly drying the spotted TLC plate with a stream of air. After 25 minutes, the mixture was added to 10mg (0.015mmol) 31 in 1 mL anhydrous DMF. After 2 hours, the solvent was removed by vacuum centrifugation and the final product was purified by reverse-phase HPLC (Vydac C-18 prep-scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield 5.4 mg.

25

30

27. 1,2,14,15-octadeutero-1,15-diamino-5,8,11-trioxapentadecane (33) As referenced in  $\delta$ Polyether Diamine Linker Synthesis, Second Generation

35

28. Deuterated analog of 31 (34) 25mg (0.07mmol) 20 was added to a stirred solution of 100mg (0.4mmol) 11 in 5 mL 0.2M sodium carbonate, pH 10.5 at 37°C. The reaction was allowed to proceed for 3 days, after which the solution was neutralized with dilute trifluoroacetic acid and purified by reverse-phase HPLC (Vydac C-18 prep-scale column, 6 mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield 7 mg.

40

45

29. SFD internal standard conjugate (35) A 4mg (12.6 $\mu$ mol) quantity of 4 was dissolved in 1 mL anhydrous DMF with stirring, under argon atmosphere. 20 mL triethylamine was added, followed by 4mg

50

55

5 (14mmol) 1. The formation of active ester was monitored by silica  
TLC (5:1 CHCl<sub>3</sub>/CH<sub>3</sub>OH, R<sub>f</sub> 0.5, UV) by briefly drying the spotted TLC  
plate with a stream of air. After 20 minutes, the mixture was added to  
10 7mg (11mmol) 34 in 1 mL anhydrous DMF. After 4 hours, the solvent  
was removed by vacuum centrifugation and the final product was  
purified by reverse-phase HPLC (Vydac C-18 prep-scale column, 6  
mL/min. Mobile phase: H<sub>2</sub>O (0.08%TFA)/ ACN (0.08%TFA)). Yield 2. 7  
15 mg.

N-(d-Biotinyl-sarcosinyl)-12-aminododecanoic acid (36). Compound 4 (32.2 mg, 0.102  
20 mmole) was dried overnight in vacuo (with P<sub>2</sub>O<sub>5</sub>). Dry DMF (2 mL) was added and the  
mixture was stirred with warming to affect dissolution under nitrogen. Triethylamine (34  
mL) was added followed by 1 (20.4 mL, 0.115 mmole) added in two 10.2 mL  
portions, 5 min apart. The mixture was stirred for 1 hr at room temperature under  
25 nitrogen. 12-Aminododecanoic acid (24.1 mg, 0.112 mmole, Sigma) was added in one  
portion, and the mixture was stirred at room temperature for 2 hr under nitrogen. CHCl<sub>3</sub>  
(80 mL) was added, and the organic solution was washed with two 10 mL portions of 1  
M HCl. CHCl<sub>3</sub> was removed by rotary evaporation, and residual DMF was removed by  
30 vacuum centrifugation. The compound was dissolved in methanol and purified by HPLC  
(Vydac 218TP prep column). Solvent program is: 0-10 min, water with 0.06% TFA; 10-  
55 min, 0-100% methanol with 0.06% TFA, flow rate is 6 mL/min. Yield 31.7 mg. 1H-  
NMR. ESI-MS, calculated 513.4, observed 513.4 (M + H)<sup>+</sup>  
35

N-hydroxysuccinimidyl ester of 36 (37). Compound 36 (9.8 mg, 19 mmole) is dissolved  
in 100 mL of dry DMF under nitrogen. N-hydroxysuccinimide (2.2 mg, 19 mmole)  
40 was added followed by dicyclohexylcarbodiimide (3.9 mg, 19 mmole). The mixture  
was stirred at room temperature for 60 h in the dark. Solvent was removed by vacuum  
centrifugation, and the residue was submitted to flash chromatography on silica gel using  
a gradient of CHCl<sub>3</sub>/CH<sub>3</sub>OH (15/1) to CHCl<sub>3</sub>/CH<sub>3</sub>OH (12/1). Yield 9.8 mg. 1H-NMR.  
45 ESI-MS, calculated 610.8, observed 609.7 (M + H)<sup>+</sup>

N-(N-(d-Biotinyl-sarcosinyl)-12-aminododecanoyl)-psychosine (38). Compound 37 (6.2  
50

5 mg, 10  $\mu$ mole) and psychosine (4.7 mg, 10  $\mu$ mole, Sigma) were dissolved in 200  
mL of dry DMF under nitrogen. Diisopropylethylamine (5 mL) was added, and the  
mixture was stirred under nitrogen for 2 days in the dark. The compound was injected  
10 directly onto the HPLC column (Vydac 218TP semi-prep), and the column was  
developed at 2 mL/min with 0-20 min, water with 0.06% TFA, then 20-80 min, 0-100%  
methanol with 0.06% TFA. Yield 3.8 mg.  $^1\text{H-NMR}$ . ESI-MS, calculated 957.3, observed  
956.8 (M + H) $^+$

15 N-(N-(d-Biotinyl-sarcosinyl)-12-aminododecanoyl)-sphingosylphosphorylcholine (39).  
Sphingosylphosphorylcholine (4.0 mg, Sigma) was mixed with 1 mL dry DMF and  
solvent was removed by vacuum centrifugation. This was repeated two more times. The  
20 final dried residue weighed 2.5 mg (5.4  $\mu$ mole). To this residue was added 3.3 mg of  
37 (5.4  $\mu$ mole), 150 mL of dry DMF, and 2.5 mL of diisopropylethylamine. The  
mixture was stirred under nitrogen in the dark for 3 days. The compound was injected  
25 directly onto the HPLC column (Vydac 218TP semi-prep), and the column was  
developed at 2 mL/min with 0-20 min, water with 0.06% TFA, then 20-80 min, 0-100%  
methanol with 0.06% TFA. Yield 3.8 mg.  $^1\text{H-NMR}$ . ESI-MS, calculated 960.3, observed  
958.7 (M + H) $^+$

30  
35 Conjugate of d-biotin with 1,13-diamino-4,7,10-trioxatridecane (40). Compound 2 was  
reacted with 1,13-diamino-4,7,10-trioxatridecane (Fluka) essentially as described for the  
synthesis of 3. The product was purified by HPLC (Vydac 218TP, semi-prep) using 0-  
100% methanol with 0.06% TFA over 30 min at 1.5 mL/min.

40 Iodoacetylated 40 (41). Compound 40 was treated with 5 equivalents of iodoacetic  
anhydride (Aldrich) in dry DMF with stirring under nitrogen for 4 h at room temperature.  
The product was purified on HPLC as for 40. The structure was confirmed by ESI-MS.

45 Octadeuterated 41 (42). The title compound was prepared as for the 40 using 9 instead  
of 1,13-diamino-4,7,10-trioxatridecane.

5

Octadeuterated 42 (43). The title compound was prepared from 42 as for 41. The structure was confirmed by ESI-MS.

45

An automated LC-MS/MS system for the identification of proteins by their amino acid sequence has been developed. A schematic representation is shown in Fig. 7. The system, which consists of an autosampler, a capillary HPLC system connected on-line to an ESI triple quadrupole MS/MS instrument and a data system is operated in the following way: Proteins (typically separated by 1D or 2D gel electrophoresis) are cleaved with a specific protease, usually trypsin. The resulting cleavage fragments are placed in an autosampler. Every 37 minutes the autosampler injects one sample into the HPLC system and the peptides are separated by capillary reverse-phase chromatography. As separated peptides elute from the chromatography column, they are ionized by the ESI process, enter the MS and the mass to charge ratio ( $m/z$ ) is measured. Any peptide ion whose intensity exceeds a predetermined intensity threshold is automatically selected by the instrument and collided in the collision cell with inert gas. These collisions result in peptide fragmentation, primarily at the bonds of the peptide backbone (collision induced dissociation, CID). The masses of the CID fragments are measured and recorded in the data system. The CID spectrum of a peptide contains sufficient information to identify the protein by searching sequence databases with the uninterpreted MS/MS spectra. This is accomplished with the Sequent program. The program identifies each peptide in a sequence database which has the same mass as the peptide that was selected in the MS for CID and predicts the MS/MS spectrum for each one of the isobaric peptides. By matching the experimentally determined CID spectrum with computer generated theoretical CID spectra, the protein from which the observed peptide originated is identified. The system is capable of analyzing protein samples in a fully automated fashion at a pace of less than 40 min. per sample. Since each peptide represents an independent protein identification and usually multiple peptides are derived from one protein, protein identification by this method is redundant and tolerant to proteins co-migrating in a gel. The system is well suited for the detection and characterization of modified residues within polypeptide chains. The LC-MS/MS technique and automated analysis of the generated CID spectra can be used for the methods of this invention.

50

**Identification of proteins at sub-femtomole sensitivity by solid-phase extraction capillary electrophoresis tandem mass spectrometry (SPE-CE-MS/MS)**

Protein identification by this method is based on the same principle as described above, except that peptide separation and ionization are performed at significantly higher

55

5 sensitivity. Fig.8 shows a schematic representation of the key design elements. The design  
of the system and its mode of operation have been published. Peptides derived from protein  
digests are concentrated by SPE, separated by CE and analyzed by ESI-MS/MS. The  
10 resulting uninterpreted CID spectra are used to search sequence databases with the  
Sequest software system. The SPE extraction device is a small reversed-phase  
chromatography column of the dimensions 0.18 x 1 mm which is directly packed in a fused  
silica separation capillary. Peptides contained in a sample solution are adsorbed and  
15 concentrated on the SPE device, eluted in an estimated 100 - 300 nl of organic solvent and  
further concentrated by electrophoretic stacking and/or isotachopheresis to an estimated  
volume of 5-30 nl. The peptides are then separated by CE in a 20  $\mu$ m or 50  $\mu$ m i.d. capillary  
and directly ionized by ESI as they leave the capillary (see reference 13 for design of the  
20 microspray ionization source). With this system, peptide masses can be determined at a  
sensitivity of 660 attomoles (approx. 500 fg for a 20 residue peptide) at a concentration limit  
of 33 amol/ $\mu$ l and that proteins can be identified by the CID spectra of automatically selected  
25 peptides at less than 10 fmol (0.5 ng for a protein of 50 kDa) of sample at a concentration  
limit of less than 300 amol/ $\mu$ l. this technique is used for the analysis at very high sensitivity  
of the peptide samples generated by the experiments. It has also been demonstrated that  
the analysis time available for automated CID experiments can be significantly extended by  
30 data-dependent modulation of the CE voltage. If several peptide ions are detected  
coincidentally in the MS, the CE voltage is automatically dropped. This results in a reduction  
of the electroosmotic flow out of the capillary and therefore in an extension of the time period  
available for selecting peptide ions for CID. The net effect of this peak parking technique is  
35 an extension of the dynamic range of the technique because the increased time available is  
used for CID of ions with a low ion current. Once all the peptide ions are analyzed,  
electrophoresis is automatically reaccelerated by increasing the CE voltage to the original  
40 value.

TABLE 1. Relative, redundant quantitation of  $\alpha$ -lactalbumin abundance (after mixing with known amount of the same protein with cysteines modified with isotopically heavy biotinylating reagent)

Peptide #	m/z (light)	Charge state	Peptide Sequence	Ratio (heavy:light)
1	518.4	2+	(K) IWCK	2.70
2	568.4	2+	(K) ALCSEK	2.68
3	570.4	2+	(K) CEVFR	2.90
4	760.5	2+	(K) LDQWLCEK	2.82

10

\* Gene names are according to the Yeast Proteome Database (YPD) (19).

# CysteinyI residue is ICAT-labeled.

\* Protein expression ratios were calculated as described in Fig. 3.

15

\* Carbon source for yeast growth was 2% ethanol (Eth) or 2% galactose (GAL0).

\* Gene is known to be galactose- or glucose-repressed (19).

\* Eight other ribosomal proteins were detected at similar gene expression levels.

TABLE - 4

Disease	Enzyme	Dysfunction
Butyrylcholinesterase deficiency	BCHE	Decreased or absent enzyme activity
Essential fructosuria hepatic fructokinase deficiency	Fructokinase	Deficient enzyme activity
Hereditary fructose intolerance	Fructose 1,6-bisphosphate aldolase B	Deficient enzyme activity
Hereditary fructose 1,6-diphosphatase deficiency	Fructose 1,6-bisphosphatase	Deficient enzyme activity
Erythrocyte aldolase deficiency with nonspherocytic hemolytic anemia (aldolase A deficiency)	Fructose 1,6-bisphosphate aldolase A	Deficient enzyme activity
Glycogen storage disease type Ia (von Gierke disease)	Glucose 6-phosphatase	Absent or deficient enzyme activity
Glycogen storage disease type Ib	Glucose 6-phosphate translocase	Deficient transport of glucose 6-phosphate across the membrane of endoplasmic reticulum
Glycogen storage disease type III	Amylo-1, 6-glucosidase (debrancher enzyme)	Absent or deficient enzyme activity
Glycogen storage disease type IV (Andersen disease)	$\alpha$ -1, 4 glucan-8- $\alpha$ -glucosyltransferase	Deficient enzyme activity
Glycogen storage disease type V (McArdle disease)	Muscle glycogen phosphorylase	Absent or deficient enzyme
Glycogen storage disease X-linked phosphorylase kinase deficiency	Phosphorylase b-kinase	Deficient or absent enzyme activity function
Glycogen storage disease autosomal phosphorylase kinase deficiency	Phosphorylase b-kinase	Deficient enzyme activity
Glycogen storage disease liver phosphorylase deficiency	Liver phosphorylase	Deficient enzyme activity
Glycogen storage disease type VII (Tarui disease)	Muscle phosphofructokinase 1	Deficient enzyme activity
Liver glycogen synthase deficiency	Liver glycogen synthase	Unknown

TABLE - 4

Disease	Enzyme	Dysfunction
Phosphoglycerate kinase deficiency	Phosphoglycerate kinase	Deficient enzyme
Phosphoglycerate mutase deficiency	Phosphoglycerate mutase	Deficient enzyme
Muscle lactate dehydrogenase deficiency	Muscle-specific subunit of lactate dehydrogenase (LDH)	Absence of M subunit of LDH. Muscle LDH is a tetramer of the heart-specific subunit
Glucose phosphate isomerase deficiency	Glucose phosphate isomerase	Unknown
Transferase deficiency galactosemia	Galactose 1-phosphate uridylyltransferase	Deficient enzyme activity
Galactokinase deficiency galactosemia	Galactokinase	Deficient enzyme activity
Epimerase deficiency galactosemia	Uridine diphosphate galactose-4-epimerase	Deficient enzyme action in blood cells only (benign) or, more rarely, in all tissues (generalized)
Phenylketonuria (PKU) due to PAH deficiency	Phenylalanine hydroxylase (PAH)	Deficient or absent PAH activity (<1% normal)
Hyperphenylalaninemia due to DHPR-deficiency	Dihydropteridine reductase (DHPR)	Deficient or absent DHPR activity
Hyperphenylalaninemia due to GTP-CH-deficiency	Guanosine triphosphate cyclohydrolase (GTP-CH)	Deficient enzyme activity
Hyperphenylalaninemia due to 6-PTS-deficiency	6-Pyruvoyl tetrahydropterin synthase (6-PTS)	Deficient enzyme activity
Oculocutaneous tyrosinemia (tyrosinemia type II; tyrosine amino-transferase deficiency)	Tyrosine aminotransferase	Decreased activity
4-Hydroxyphenylpyruvic acid dioxygenase (tyrosinemia type III)	4-Hydroxy-phenylpyruvic acid dioxygenase	Decreased activity
Maleylacetoacetate isomerase deficiency (tyrosinemia type Ib) (tentative)	Maleylacetonacetate isomerase	Presumably decreased enzyme activity

TABLE - 4

Disease	Enzyme	Dysfunction
Hepatorenal tyrosinemia (tyrosinemia type I: fumarylacetoacetate hydrolase deficiency)	Fumarylacetoacetate hydroxylase	Deficient enzyme activity
Carbamyl phosphate synthetase deficiency	Carbamyl phosphate synthetase I	Absent or deficient enzyme activity
Ornithine transcarbamylase deficiency	Ornithine transcarbamylase	Absent or reduced enzyme activity
Argininosuccinic acid synthetase deficiency	Argininosuccinic acid synthetase	Deficient enzyme activity
Argininosuccinase deficiency	Argininosuccinate lyase	Deficient enzyme activity
Arginase deficiency	Liver arginase	Deficient enzyme activity
Familial hyperlysinemia (variant: saccharopinuria)	$\alpha$ -Aminoadipic semialdehyde synthase	Deficient enzyme activity
Maple syrup urine disease (MSUD) or branched chain ketoacidemia	Branched-chain $\alpha$ -keto acid dehydrogenase	Deficient or absent (<2%) BCKAD complex activity in mitochondria; immunologic absence or reduced levels of enzyme subunits; impairment of E1 subunit assembly
Cystathionine $\beta$ -synthase deficiency	Cystathionine $\beta$ -synthase	Deficient enzyme activity
$\alpha$ -Cystathionase deficiency	$\alpha$ -Cystathionase	Deficient enzyme activity
Hepatic methionine adenosyltransferase deficiency	Isoenzyme of methionine adenosyltransferase	Deficient enzyme activity
Sarcosinemia	Sarcosine dehydrogenase?	Deficient enzyme activity
Nonketotic hyperglycinemia	Glycine cleavage system	Deficient enzyme activity
Hyperuracil thymineuria	Dihydropyrimidine dehydrogenase	Deficient enzyme activity
Dihydropyrimidinuria	Dihydropyrimidinase	Unknown
Pyridoxine dependency with seizures	Brain glutamic acid decarboxylase-1	Deficient coenzyme binding? (brain)

TABLE - 4

Disease	Enzyme	Dysfunction
GABA aminotransferase deficiency	GABA- $\alpha$ -ketoglutarate transaminase	Deficient enzyme activity
4-Hydroxybutyric aciduria	Succinic semialdehyde dehydrogenase	Deficient enzyme activity
Serum carnosinase deficiency and homocarnosinosis	Serum carnosinase	Deficient enzyme
Alkaptonuria	Homogentisic acid oxidase	Absent or deficient enzyme activity
Isovaleric acidemia	Isovaleryl-CoA dehydrogenase	Deficient enzyme activity, deficient protein, abnormal peptide size
Isolated 3-methylcrotonyl-CoA carboxylase deficiency	3-Methylcrotonyl-CoA carboxylase	Deficient enzyme activity
3-Methylglutaconic aciduria - Mild form:	3-Methylglutaconyl-CoA hydratase	Deficient enzyme activity
3-Hydroxy-3-methylglutaryl-CoA lyase deficiency	3-Hydroxy-3-methylglutaryl-CoA lyase	Deficient enzyme activity
Mevalonic aciduria	Mevalonate kinase	Deficient enzyme activity
Mitochondrial acetoacetyl-CoA thiolase deficiency	Mitochondrial acetoacetyl-CoA thiolase (T2)	Deficient enzyme activity, decreased protein, unstable protein
Propionic acidemia (2 nonallelic forms designated <i>pccA</i> and <i>pccBC</i> )	Propionyl-CoA carboxylase (PCC)	Deficient enzyme activity (nonallelic forms reflect mutations in nonidentical subunits of PCC)
Methylmalonic acidemia (2 allelic variants designated <i>mut</i> <sup>+</sup> and <i>mut</i> <sup>-</sup> )	Methylmalonyl-CoA mutase (MUT) apoenzyme	Absent MUT activity in <i>mut</i> <sup>+</sup> , deficient MUT activity due to reduced affinity for cofactor (adenosylcobalamin) in <i>mut</i> <sup>-</sup>
Glutaric acidemia type I	Glutaryl-CoA dehydrogenase	Deficient enzyme activity
Cytochrome oxidase deficiency	Cytochrome oxidase polypeptides	Decreased activity of the cytochrome oxidase complex

TABLE - 4

Disease	Enzyme	Dysfunction
Pyruvate dehydrogenase complex deficiency-E <sub>1</sub> decarboxylase component	Pyruvate decarboxylase, E <sub>1</sub> $\alpha$	Decreased enzyme activity, decreased protein
Pyruvate dehydrogenase E <sub>2</sub> transacylase	Dihydrolipoamide transacylase	Decreased enzyme activity; abnormal protein electrophoretic mobility
Combined $\alpha$ -ketoacid dehydrogenase deficiency/lipoamide dehydrogenase deficiency	Lipoamide dehydrogenase	Decreased enzyme activity
Pyruvate carboxylase deficiency	Pyruvate carboxylase	Absent enzyme activity; 7 cases absent enzyme, protein, and mRNA
Carnitine palmitoyl transferase I (CPT I) deficiency	Carnitine palmitoyl transferase I	Deficient enzyme
Carnitine/acyl/carnitine translocase deficiency	Carnitine/acylcarnitine translocase	Deficient translocase
Carnitine palmitoyl transferase II (CPT II) deficiency	Carnitine palmitoyl transferase II	Deficient enzyme
Very long-chain acyl-CoA dehydrogenase (VLCAD) deficiency	Very long-chain acyl-CoA dehydrogenase	Deficient enzyme
Long-chain acyl-CoA dehydrogenase (LCAD)	Long-chain acyl-CoA dehydrogenase	Deficient enzyme
Long-chain L-3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency	L-3-hydroxyacyl-CoA dehydrogenase	Deficient enzyme
Trifunctional enzyme (TFE) deficiency	Trifunctional enzyme	Deficient enzyme
Dienoyl-Co reductase deficiency	2,4-dienoyl-CoA reductase	Deficient enzyme
Medium-chain acyl-CoA dehydrogenase (MCAD) deficiency	Medium-chain acyl-CoA dehydrogenase	Deficient enzyme
Short-chain acyl-CoA dehydrogenase (SCAD) deficiency	Short-chain acyl-CoA dehydrogenase	Deficient enzyme

TABLE - 4

Disease	Enzyme	Dysfunction
Glutaric acidemia type II	Electron transfer flavoprotein (ETF); ETF:ubiquinone oxidoreductase	In some cases, no enzyme antigen; in others, no enzyme activity
Glycerol kinase deficiency (Gkd)	Glycerol kinase	The microdeletion involves not only GK but also the other deleted loci: <i>AHC</i> , <i>DMD</i> , <i>OTC</i> , and other linked loci
Primary gout: superactive variant of phosphoribosylpyrophosphate (PP-ribose-P) synthetase	PP-ribose-P synthetase	Enhanced enzyme activity
Primary gout: partial deficiency of hypoxanthine guanine phosphoribosyltransferase (HPRT)	Hypoxanthine guanine phosphoribosyltransferase (HPRT)	Absent or deficient enzyme activity
Lesch-Nyhan syndrome: deficiency of hypoxanthine guanine phosphoribosyltransferase (HPRT)	Hypoxanthine guanine phosphoribosyltransferase (HPRT)	Absent or deficient enzyme activity
2,8-Dihydroxyadenine lithiasis (adenine phosphoribosyltransferase deficiency)	Adenine phosphoribosyltransferase	Type I: absent enzyme activity; type II: reduced affinity for PP-ribose-P
Adenosine deaminase deficiency with severe combined immunodeficiency disease	Adenosine deaminase	Absent or greatly diminished enzyme activity
Purine nucleoside phosphorylase deficiency with cellular immunodeficiency	Purine nucleoside phosphorylase	Absent or greatly diminished enzyme activity
Myoadenylate deaminase deficiency	Myoadenylate deaminase (AMPD1)	No enzyme activity; on immunoreactive protein
Xanthinuria	Xanthine dehydrogenase (xanthine oxidase)	Type I: absent xanthine dehydrogenase activity; type II: absent xanthine dehydrogenase and aldehyde oxidase activity

TABLE - 4

Disease	Enzyme	Dysfunction
Hereditary orotic aciduria	UMP synthase	Deficient enzyme activity (unstable protein)
Pyrimidine 5'-nucleotidase deficiency	Pyrimidine 5'-nucleotidase	Absent or unstable enzyme
Dihydropyrimidine dehydrogenase deficiency	Dihydropyrimidine dehydrogenase	Absent or unstable enzyme
Dihydropyrimidase deficiency	Dihydropyrimidase	Absent or unstable enzyme
Familial lipoprotein lipase deficiency	Lipoprotein lipase	Nonfunctional protein in some, nondetectable enzyme activity and protein in others
Familial lecithin:cholesterol acyltransferase deficiency	Lecithin:cholesterol acyltransferase	Absent enzyme protein or deficient enzyme activity
$\delta$ -Aminolevulinic acid dehydratase porphyria	$\delta$ -Aminolevulinic acid dehydratase	Minimal enzyme activity
Acute intermittent porphyria	Porphobilinogen deaminase	Decreased enzyme activity (~50%)
Congenital erythropoietic porphyria	Uroporphyrinogen III cosynthase	Minimal enzyme activity
Porphyria cutanea tarda (familial form)	Uroporphyrinogen decarboxylase	Decreased enzyme activity (~50%)
Hepatoerythropoietic porphyria	Uroporphyrinogen decarboxylase	Minimal enzyme activity
Hereditary coproporphyria	Coproporphyrinogen oxidase	Decreased enzyme activity (~50%)
Variegate porphyria	Protoporphyrinogen oxidase	Decreased enzyme activity (~50%)
Erythropoietic protoporphyria	Ferrochelatase	Decrease enzyme activity (~50%)
Crigler-Najjar syndrome, type I	Bilirubin UDP-glucuronosyltransferase	Absent enzyme activity
Crigler-Najjar syndrome, type II	Bilirubin UDP-glucuronosyltransferase	Markedly reduced enzyme activity

TABLE - 4

Disease	Enzyme	Dysfunction
Gilbert syndrome	Bilirubin UDP-glucuronosyltransferase activity	Reduced enzyme activity
Refsum disease	Phytanic acid $\alpha$ -hydroxylase	Deficient enzyme activity
Primary hyperoxaluria type I	Alanine-glyoxylate aminotransferase	Loss of enzyme catalytic activity and aberrant subcellular distribution
Primary hyperoxaluria type 2	Glyoxylate reductase/D-glycerate dehydrogenase	Loss of enzyme catalytic activity
G <sub>M2</sub> gangliosidosis: hexosaminidase $\alpha$ -subunit deficiency (variant B, Tay-Sachs disease)	$\beta$ -hexosaminidase	Absent or defective hexosaminidase A ( $\alpha\beta$ ) activity
Glycogen storage disease type II	$\alpha$ -glucosidase	Absent or deficient enzyme activity
Mucopolysaccharidosis I (Hurler, Scheie, and Hurler-Scheie syndromes, MPS, MPS IS, MPS IH/S)	$\alpha$ -L-iduronidase	Absent enzyme activity
Mucopolysaccharidosis II (Hunter syndrome)	Iduronate sulfatase	Absent enzyme activity
Mucopolysaccharidosis III (Sanfilippo syndrome) types A, B, C and D	IIIA: Heparan N-sulfatase IIIB: $\alpha$ -N-acetylglucosaminidase IIIC: Acetyl-CoA: $\alpha$ -glucosaminide acetyltransferase IIID: N-acetylglucosamine-6-sulfatase	Absent enzyme activity
Mucopolysaccharidosis IV (Morquio syndrome) types A and B	IVA: Galactose 6-sulfatase IVB: $\beta$ -Galactosidase	Absent enzyme activity
Mucopolysaccharidosis VI (Maroteaux-Lamy syndrome)	N-acetyl-galactosamine 4-sulfatase	Absent enzyme activity
Mucopolysaccharidosis VII (Sly syndrome)	$\beta$ -glucuronidase	Absent enzyme activity

TABLE - 4

Disease	Enzyme	Dysfunction
I-cell disease (ML-II)	N-acetylglucosaminyl-1-phosphotransferase	Phosphorylation of many lysosomal enzymes
Schindler disease ( $\alpha$ -N-acetyl-galactosaminidase deficiency)	$\alpha$ -N-acetyl-galactosaminidase	Deficient activity of $\alpha$ -N-acetyl-galactosaminidase
$\alpha$ -Mannosidosis	$\alpha$ -D-mannosidase	Deficient or unstable enzyme activity
$\beta$ -Mannosidosis	$\beta$ -D-mannosidase	Deficient enzyme activity
Sialidosis	$\alpha$ -neuraminidase	Deficient enzyme activity
Aspartylglucosaminuria	Aspartylglucosaminidase	Deficient enzyme activity
Fucosidosis	$\alpha$ -L-fucosidase	Deficient enzyme activity
Wolman disease and cholesteryl ester storage disease	Acid lipase	Deficient enzyme activity
Ceramidase deficiency (Farber lipogranulomatosis)	Ceramidase	Deficient enzyme activity
Niemann-Pick disease (NPD) types A and B (primary sphingomyelin storage)	Sphingomyelinase	Deficient sphingomyelinase activity
Gaucher disease type I (nonneuronopathic)	Glucocerebrosidase	Decreased catalytic activity and some instability of enzyme protein
Globoid-cell leukodystrophy (Krabbe disease)	Galactosylceramidase	Absent enzyme activity
Metachromatic leukodystrophy	Arylsulfatase A	Deficient enzyme activity
Fabry disease	$\alpha$ -Galactosidase A	Nonfunctional or unstable enzyme protein
G <sub>M1</sub> gangliosidosis	Acid $\beta$ -galactosidase (GLB1)	Deficient enzyme activity
G <sub>M2</sub> gangliosidosis: hexosaminidase $\alpha$ -subunit deficiency (variant B, Tay-Sachs disease)	$\beta$ -hexosaminidase	Absent or defective hexosaminidase A ( $\alpha\beta$ ) activity
Steroid 21-hydroxylase deficiency salt-losing form	Steroid 21-hydroxylase	Absent or truncated enzyme with no activity

TABLE - 4

Disease	Enzyme	Dysfunction
Steroid 5 $\alpha$ -reductase 2 deficiency	Steroid 5 $\alpha$ -reductase 2	Absent or unstable enzyme activity
Steroid sulfatase deficiency (X-linked ichthyosis)	3 $\beta$ -hydroxysteroid sulfatase	Absent immunoreactive and enzymatically active protein (both deletion and nondeletion patients)
Methylenetetrahydrofolate reductase deficiency	Methylenetetrahydrofolate reductase	Absent or deficient enzyme activity. Thermolabile variants have been described.
Holocarboxylase synthetase deficiency	Holocarboxylase synthetase	Deficient holocarboxylase synthetase activity
Biotinidase deficiency	Biotinidase	Deficient biotinidase activity
Hereditary methemoglobinemia secondary to cytochrome b <sub>5</sub> reductase deficiency, types I, II, and III	Cytochrome b <sub>5</sub> reductase	Deficient enzyme activity in erythrocyte cytosol only (type I), in all tissues (type II), and in all hematopoietic cells (type III)
Pyruvate kinase deficiency hemolytic anemia	Pyruvate kinase	Deficient enzyme activity
Hexokinase deficiency hemolytic anemia	Hexokinase	Deficient enzyme activity
Glucosephosphate isomerase deficiency hemolytic anemia	Glucosephosphate isomerase	Deficient enzyme activity
Aldolase deficiency hemolytic anemia	Aldolase (A type)	Deficient enzyme activity
Triosephosphate isomerase deficiency hemolytic anemia	Triosephosphate isomerase	Enzyme activity deficient in all tissues
Phosphoglycerate kinase deficiency hemolytic anemia	Phosphoglycerate kinase	Deficient enzyme activity in hemizygotes
2,3-Diphospho-glyceromutase and phosphatase deficiency	2,3-Diphospho-glyceromutase and phosphatase (1 protein)	Deficient enzyme activity
6-Phosphogluconate dehydrogenase deficiency	6-Phosphogluconate dehydrogenase	Enzyme activity deficiency

TABLE - 4

Disease	Enzyme	Dysfunction
Glutathione peroxidase deficiency	Glutathione peroxidase	Diminished enzyme activity
Glutathione reductase deficiency	Glutathione reductase	Deficient enzyme activity
Glutathione synthetase deficiency hemolytic anemia	Glutathione synthetase	Deficient enzyme activity
$\gamma$ -Glutamylcysteine synthetase deficiency hemolytic anemia	$\gamma$ -Glutamylcysteine synthetase	Deficient enzyme activity
Adenosine deaminase hyperactivity hemolytic anemia	Adenosine deaminase	Overproduction of structurally normal enzyme protein mediated at mRNA translation level
Pyrimidine nucleotidase deficiency hemolytic anemia	Pyrimidine nucleotidase	Deficient enzyme activity
Myeloperoxidase deficiency	Myeloperoxidase	Absent or deficient enzyme activity
Carbonic anhydrase II deficiency syndrome (osteopetrosis with renal tubular acidosis)	Carbonic anhydrase II	Quantitative deficiency of carbonic anhydrase II
Albinism, oculocutaneous tyrosinase-negative type (OCA1A)	Tyrosinase	Absent, reduced, or unusual enzyme activity
Canavan disease	Aspartoacylase	Deficient enzyme activity

TABLE 5. Molecular masses of protonated and sodiated substrate-conjugates, products, and internal standards for CDGS enzymes.

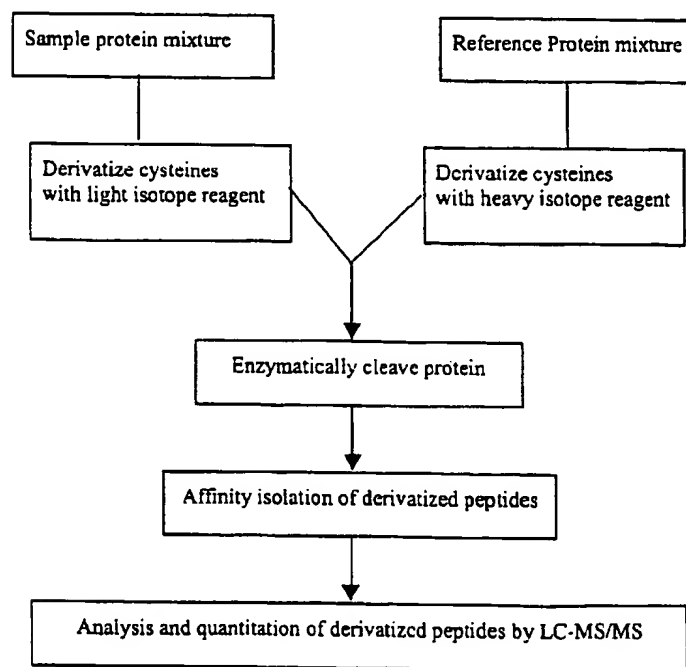

Enzyme	Substrate		Product		Internal standard	
	(M + H) <sup>+</sup>	(M + Na) <sup>+</sup>	(M + H) <sup>+</sup>	(M + Na) <sup>+</sup>	(M + H) <sup>+</sup>	(M + Na) <sup>+</sup>
Type Ia,b	711	733	549	571	555	577
Manose-transferase	725	747	563	585	570	592
Type II	1156	1178	1343	1365	1348	1370
Type	1126	1148	2362 <sup>a</sup>	2384 <sup>a</sup>	2367 <sup>a</sup>	2389 <sup>a</sup>

<sup>a</sup> Calculated for the GlcNAc-T II product and internal standard contain a GlcNAc-GlcNAc-Mannose-(Mannose-GlcNAc)<sub>2</sub> residue.

Scheme 1

Flowchart illustration of the procedure for quantitative protein profile measurements based on stable isotope ratios by mass spectrometry

## Scheme 2

Custom chemical synthesis of sulfhydryl-reactive biotinylating reagent. Linker can be made either isotopically heavy (d8) or light(d0).

## Scheme 3

Synthesis of reagent specific for biotinylation of free amino groups. The reagent is synthesized in both isotopically heavy (d8) or light (d0) form.

## Claims

5

10

15

20

25

30

35

40

45

50

55

5

We claim:

1. A method for identifying one or more proteins or protein functions in one or more samples containing mixtures of proteins which comprises the steps of:

10

(a) providing an affinity tagged, substantially chemically identical and differentially isotopically labeled protein reactive reagent for each sample wherein the reagent has the formula:

A-L-PRG

15

where A is an affinity label that selectively binds to a capture reagent, L is a linker group in which one or more atoms can be differentially labelled with one or more stable isotopes and PRG is a protein reactive group that selectively reacts with certain protein functional groups or is a substrate for an enzyme;

20

(b) reacting each sample with one of the protein reactive reagents to provide affinity tagged proteins or affinity tagged enzyme products in the sample, affinity tagged proteins and enzyme products in different samples being thereby differentially labeled with stable isotopes;

25

(c) capturing affinity tagged components of the samples using the capture reagent that selectively binds A;

30

(d) releasing captured affinity tagged components from the capture reagent by disrupting the interaction between the affinity tagged components and the capture reagent; and

(e) detecting and identifying the released affinity tagged components by mass spectrometry.

35

2. The method of claim 1 wherein the affinity tagged proteins in the samples are enzymatically or chemically processed before or after their capture to convert them into affinity tagged peptides.

3. The method of claim 2 wherein the protein portion of one or more of the affinity tagged proteins are sequenced by tandem mass spectrometry to identify the affinity tagged protein from which the peptide originated.

40

4. The method of claim 1 wherein the protein portion of one or more of the affinity tagged proteins are sequenced by tandem mass spectrometry to identify the protein.

45

5. The method of claim 1 in which the amount of one or more proteins in the samples is also determined by mass spectrometry and which further comprises the step of introducing into a sample a known amount of one or more internal standards for each of the proteins to be quantitated.

6. The method of claim 1 wherein PRG is an enzyme substrate and the enzymatic

50

98

SUBSTITUTE SHEET (RULE 26)

55

- 5 velocities of one or more enzymes in a sample are determined by quantitation of  
affinity tagged enzyme products and which further comprises the step of introducing  
into a sample a known amount of one or more internal standards for each of the  
affinity tagged enzyme products of an enzyme, the velocity of which, is to be  
quantitated.
- 10 7. The method of claim 1 wherein the released affinity tagged components are  
separated by chromatography prior to detecting and identifying the components by  
mass spectrometry.
- 15 8. The method of claim 1 in which a plurality of proteins or protein functions in one  
sample are detected and identified.
- 20 9. The method of claim 1 further comprising a step in which one or more of the proteins  
in a sample are chemically or enzymatically processed to expose a functional group  
that can react with an affinity tag.
- 25 10. The method of claim 9 wherein the PRG is an enzyme substrate for one or more  
enzymes, the deficiencies of which, are linked to a disease state.
11. The method of claim 9 wherein an affinity tagged, substantially chemically identical  
and differentially isotopically labeled enzyme substrate is provided for each enzyme  
that is to be detected and identified in a sample.
- 30 12. The method of claim 1 wherein PRG is a protein reactive group that selectively reacts  
with certain protein functional groups and a plurality of proteins are detected and  
identified in a single sample.
- 35 13. The method of claim 11 wherein two or more affinity tagged, substantially chemically  
identical and differentially isotopically labeled protein reactive reagents having  
different specificities for reaction with proteins are provided and reacted with each  
sample to be analyzed.
- 40 14. The method of claim 13 wherein all of the proteins in a sample are detected and  
identified.
15. The method of claim 1 wherein the relative amounts of one or more proteins in two or  
more different samples are determined and which further comprises the steps of  
combining the differentially labeled samples, capturing affinity tagged components  
from the combined samples and measuring the relative abundances of the affinity  
tagged differentially labeled proteins or the affinity tagged differentially labeled  
peptides originating from that protein.
- 45 16. The method of claim 15 which determines the relative amounts of membrane proteins  
in one or more different samples.
17. The method of claim 15 in which different samples contain proteins originating from  
different organelles or different subcellular fractions.

5

18. The method of claim 15 in which different samples represent proteins expressed in response to different environmental or nutritional conditions, different chemical or physical stimuli or at different times.

10

19. A method for determining relative expression levels of proteins in two or more samples containing proteins which comprises the steps of:

(a) providing an affinity tagged, substantially chemically identical and differentially isotopically labeled protein reactive reagent for each sample wherein the reagent has the formula:

15

A-L-PRG

where A is an affinity label that selectively binds to a capture reagent, L is a linker group which can be differentially labelled with stable isotopes and PRG is a protein reactive group that selectively reacts with certain protein functional groups;

20

(b) reacting each sample with one of the protein reactive reagents to provide affinity tagged proteins in the sample, affinity tagged proteins in different samples, being thereby differentially labeled with stable isotopes;

25

(c) combining the differentially labeled samples and treating the combined sample to cleave the proteins therein and to generate peptides;

(d) capturing affinity tagged differentially labeled peptides of the combined sample using the capture reagent that selectively binds A;

30

(e) releasing captured affinity tagged differentially labeled peptides from the capture reagent by disrupting the interaction between the affinity tagged peptides and the capture reagent; and

(e) detecting and identifying the released affinity tagged differentially labeled peptides by mass spectrometry; and

35

(f) measuring the relative abundances of the isotopically distinct ion peaks generated from an affinity tagged differential labeled peptide to determining relative expression levels of the protein from which the affinity tagged differential labeled peptide originated.

40

20. A reagent for mass spectrometric analysis of proteins which has the general formula:

A-L-PRG

where A is an affinity label that selectively binds to a capture reagent, L is a linker group which can be differentially labelled with stable isotopes and PRG is a protein reactive group that selectively that selectively reacts with certain protein functional groups.

45

50

100

SUBSTITUTE SHEET (RULE 26)

55

- 5
21. The reagent of claim 20 wherein PRG is a sulfhydryl reactive group or an amine reactive group.
22. The reagent of claim 20 wherein PRG is an enzyme substrate.
- 10
23. The reagent of claim 20 wherein the A-L-PRG is soluble in a sample liquid to be analyzed.
24. The reagent of claim 20 wherein the linker is a cleavable linker.
- 15
25. The reagent of claim 20 which has the general formula:

where: A is an affinity label;

20 PRG is a protein reactive group; and

B1-X1-(CH<sub>2</sub>)<sub>n</sub>-[X2-(CH<sub>2</sub>)<sub>m</sub>]<sub>x</sub>-X3-(CH<sub>2</sub>)<sub>p</sub>-X4-B2 is a linker group wherein:

25 X1, X2, X3 and X4, independently of one another, and X2 independently of other X2, can be selected from O, S, NH, NR, NRR<sup>+</sup>, CO, COO, COS, S-S, SO, SO<sub>2</sub>, CO-NR', CS-NR', Si-O, aryl or diaryl groups or X1-X4 may be absent; B1 and B2, independently of one another, are optional groups selected from COO, CO, CO-NR', CS-NR', (CH<sub>2</sub>)<sub>q</sub>-CONR', (CH<sub>2</sub>)<sub>q</sub>-CS-NR', or (CH<sub>2</sub>)<sub>q</sub>;

30 n, m, p, q and x are whole numbers that can take values from 0 to about 100, where the sum of n+xm+p+q is less than about 100;

R is an alkyl, alkenyl, alkynyl, alkoxy or an aryl group that is optionally substituted with one or more alkyl, alkenyl, alkynyl, or alkoxy groups; and

35 R' is a hydrogen, an alkyl, alkenyl, alkynyl, alkoxy or an aryl group that is optionally substituted with one or more alkyl, alkenyl, alkynyl, or alkoxy groups

40 wherein one or more of the CH<sub>2</sub> groups in the linker can be optionally substituted with alkyl, alkenyl, alkoxy groups, an aryl group that is optionally substituted with one or more alkyl, alkenyl, alkynyl, or alkoxy groups, an acidic group, a basic group or a group carrying a permanent positive or negative charge; wherein one or more single bonds linking non-adjacent CH<sub>2</sub> groups in the linker can be replaced with a double or a triple bond and wherein one or more of the atoms in the linker can be substituted with a stable isotope.

- 45
26. The reagent of claim 20 wherein the affinity label is biotin or a modified biotin.
27. The reagent of claim 20 wherein the affinity label is selected from the group consisting of a 1,2-diol, glutathione, maltose, a nitrilotriacetic acid group, or an oligohistidine.

- 5 28. The reagent of claim 20 wherein the affinity label is a hapten.
29. The reagent of claim 20 wherein PRG is a sulfhydryl-reactive group.
- 10 30. The reagent of claim 20 wherein PRG is an iodoacetylamine group, an epoxide, an  $\alpha$ -haloacyl group, a nitrile, a sulfonated alkyl, an aryl thiols or a maleimide.
31. The reagent of claim 20 wherein PRG is an amine reactive group, a group that reacts with a homoserine lactone or a group that reacts with carboxylic acid group.
- 15 32. The reagent of claim 20 wherein PRG is selected from the groups consisting of a amine reactive pentafluorophenyl ester group, an amine reactive N-hydroxy succinimide ester group, sulfonyl halide, isocyanate, isothiocyanate, active ester, tetrafluorophenyl ester, an acid halide, and an acid anhydride; a homoserine lactone reactive primary amine group, and an carboxylic acid reactive amine, alcohols or 2,3,5,6-tetrafluorophenyl trifluoroacetate.
- 20 33. The reagent of claim 20 wherein PRG is a substrate for an enzyme.
34. The reagent of claim 20 wherein PRG is a substrate for an enzyme the deficiency of which is associated with a birth defect.
- 25 35. The reagent of claim 20 wherein PRG is a substrate for an enzyme the deficiency of which is associated with a lysosomal storage disease.
37. The reagent of claim 20 wherein PRG is a substrate for  $\beta$ -galactosidase, acetyl- $\alpha$ -D-glucosaminidase, heparan sulfamidase, acetyl-CoA- $\alpha$ -D-glucosaminide N-acetyltransferase or N-acetylglucosamine-6-sulfatase.
- 30 38. The reagent of claim 20 wherein at least one of B1 or B2 is CO-NR' or CS-NR.
39. The reagent of claim 20 wherein X1 and X4 are selected from NH, NR, and NRR', X3 is O and all X2 groups are O.
- 35 40. The reagent of claim 20 wherein the linker contains a disulfide group.
41. The reagent of claim 20 wherein any atom of the linker may be substituted with a heavy isotope.
- 40 42. A reagent kit for the analysis of proteins by mass spectral analysis that comprises a reagent of claim 20.
43. The reagent kit of claim 42 that comprises one or more reagents of claim 20.
- 45 44. The reagent kit of claim 42 further comprising one or more proteolytic enzymes for use in digestion of affinity tagged proteins.
- 45 45. The reagent kit of claim 42 which comprises a set of substantially chemically identical differentially labelled affinity tagged reagents.

5

46. The reagent kit of claim 42 wherein the reagent is an affinity tagged enzyme substrate reagent.

10

47. The reagent kit of claim 46 which comprises a set of substantially chemically identical differentially labeled affinity tagged enzyme substrates.

15

48. The reagent kit of claim 47 further comprising a set of substantially chemically identical differentially labeled affinity tagged enzyme products.

SUBSTITUTE SHEET (RULE 28)

Fig. 1A

Fig. 1B

Standard curve generated with a cysteine-biotinylated peptide and quantitation by stable isotope dilution. A) Zoom-scan from an ion-trap mass spectrometer showing a 4 amu isotope distribution for the  $[M+2H]^+$  ions of the peptide modified with the isotopically light (1457.9 u) and heavy (1461.8) biotinylating reagents. The ratio ( $d0/d8$ ) was 4.54. B) Curve generated from the analysis of isotope ratios from zoom-scans of 5 different concentrations of  $d0$ -labeled peptide measured in the presence of a known amount of peptide labeled with the isotopically heavy reagent.

Tandem mass spectrum of a cysteine-modified peptide from  $\alpha$ -lactalbumin. Modification of the cysteine residue with the custom synthesized biotinylating reagent did not affect the ability of the Sequest computer program to correctly match this peptide to a database sequence.

Fig. 5C

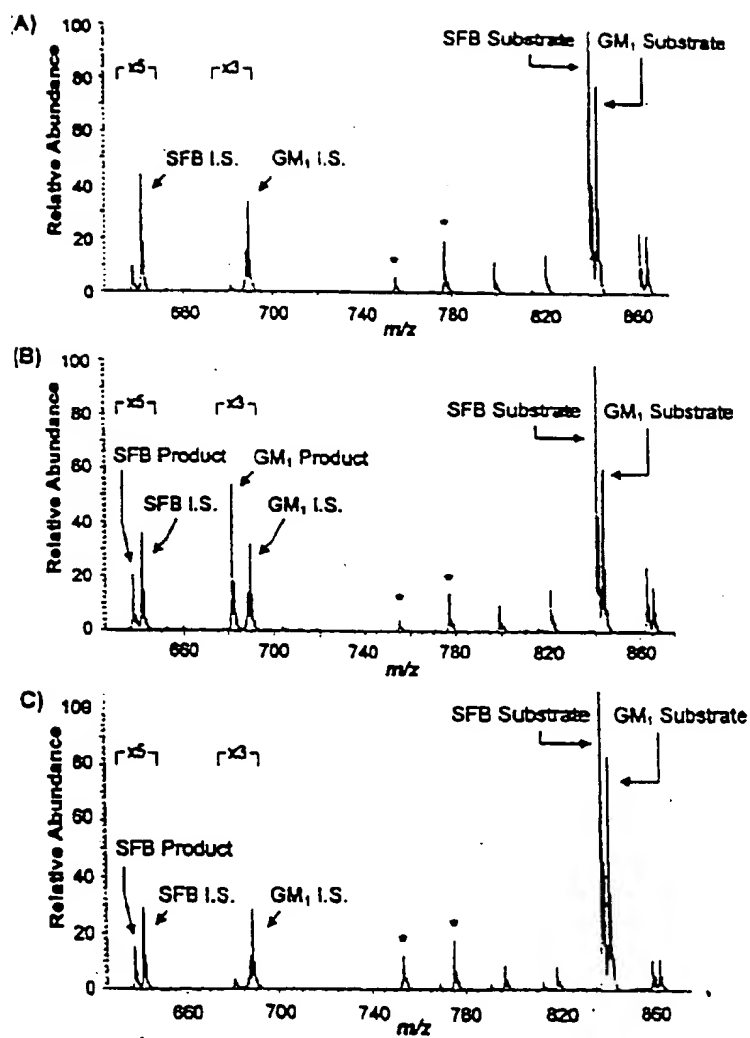

Figure 6A-C

Figure 7 Schematic representation of the automated LC-MS/MS system. Proteins are typically separated by 1D or 2D SDS-PAGE (1). Protein spots or bands are selected, excised and proteolytically cleaved with trypsin (2). Digests are loaded into an autosampler, which delivers them sequentially to the injection mechanism of a narrow-bore HPLC system (Michrom). The column gradient is automatically applied to separate individual peptides (3). Column eluate is sprayed directly into a mass spectrometer where sequence information from the peptides is collected (4). Recorded peptide masses and CID spectra are transferred to a data station for sequence analysis, and a final summary of all identifications made for all samples originally loaded is sent to a printer (5).

Figure 1 Schematic of the SPE-CE-MS/MS system. A) A fused silica capillary, typically of 50  $\mu\text{m}$  i.d., is modified at the electrospray end with a liquid junction to establish electrical contact with the analytes inside the capillary. Approx. 5 cm from the end of the capillary, the SPE device is introduced. This consists of  $\text{C}_{18}$ -derivatized, large pore silica beads packed inside a 250  $\mu\text{m}$  i.d. Teflon tubing with Teflon membranes at each end to hold the beads in place between the two fused silica capillaries. B) The injection end of the capillary is inserted into a sealed container which is maintained at a constant, slightly hyperbaric pressure in order to ensure constant flow. A platinum electrode is inserted through the cap, into the container, in order to allow the electrical contact to be made.
